BACKGROUND OF THE INVENTION

The molecular bases underlying many human and animal physiological states (e.g., diseased and homeostatic states of various tissues) remain unknown.

5 Nonetheless, it is well understood that these states result from interactions among the proteins and nucleic acids present in the cells of the relevant tissues. In the past, the complexity of biological systems overwhelmed the ability of practitioners to understand the molecular interactions giving rise to normal and abnormal physiological states. More recently, though, the techniques of molecular biology,
10 transgenic and null mutant animal production, computational biology, and pharmacogenomics have enabled practitioners to discern the role and importance of individual genes and proteins in particular physiological states.

Knowledge of the sequences and other properties of genes (particularly including the portions of genes encoding proteins) and the proteins encoded thereby
15 enables the practitioner to design and screen agents which will affect, prospectively or retrospectively, the physiological state of an animal tissue in a favorable way. Such knowledge also enables the practitioner, by detecting the levels of gene expression and protein production, to diagnose the current physiological state of a tissue or animal and to predict such physiological states in the future. This
20 knowledge furthermore enables the practitioner to identify and design molecules which bind with the polynucleotides and proteins, in vitro, in vivo, or both.

Cadherins are a class of cell-surface adhesion molecules that mediate calcium-dependent cell-to-cell adhesion. Many cadherins exhibit homophilic adhesion; i.e. they bind with molecules of the same cadherin on a different cell.
25 However, cadherins that bind specifically with other molecules have also been described (e.g. Telo et al., 1998, J. Biol. Chem. 273:17565-17572; Ludviksson et al., 1999 J. Immunol. 162:4975-4982). In addition to their binding capabilities, cadherins also exhibit transmembrane signaling and regulatable adhesion activity (e.g. Yap et al., 1997, 13:119-146; Gumbiner, 2000, J. Cell Biol. 148:399-403).

Despite the fact that numerous cadherins and cadherin-like proteins have been described, many others have not yet been characterized. A family of cadherin-like proteins which the inventor believes to be novel is described herein.

Many secreted proteins, for example, cytokines and cytokine receptors, play a vital role in the regulation of cell growth, cell differentiation, and a variety of specific cellular responses. A number of medically useful proteins, including erythropoietin, granulocyte-macrophage colony stimulating factor, human growth hormone, and various interleukins, are secreted proteins. Thus, an important goal in the design and development of new therapies is the identification and characterization of secreted and transmembrane proteins and the genes which encode them.

Many secreted proteins are receptors which bind a ligand and transduce an intracellular signal, leading to a variety of cellular responses. The identification and characterization of such a receptor enables one to identify both the ligands which bind to the receptor and the intracellular molecules and signal transduction pathways associated with the receptor, permitting one to identify or design modulators of receptor activity, e.g., receptor agonists or antagonists and modulators of signal transduction.

SUMMARY OF THE INVENTION

The present invention is based, at least in part, on the discovery of human cDNA molecules which encode proteins which are herein designated TANGO 202, TANGO 210, INTERCEPT 217, TANGO 229, TANGO 234, TANGO 265, TANGO 276, TANGO 286, INTERCEPT 289, TANGO 292, TANGO 294, INTERCEPT 296, INTERCEPT 297, INTERCEPT 309, TANGO 331, TANGO 332, TANGO 366, INTERCEPT 394, INTERCEPT 400, TANGO 416, MANGO 419, INTERCEPT 429, and TANGO 457. These proteins, fragments thereof, derivatives thereof, and variants thereof are collectively referred to herein as the polypeptides of the invention or the proteins of the invention. Nucleic acid molecules encoding

polypeptides of the invention are collectively referred to as nucleic acids of the invention.

The nucleic acids and polypeptides of the present invention are useful as modulating agents for regulating a variety of cellular processes. Accordingly, in one aspect, the present invention provides isolated nucleic acid molecules encoding a polypeptide of the invention or a biologically active portion thereof. The present invention also provides nucleic acid molecules which are suitable as primers or hybridization probes for the detection of nucleic acids encoding a polypeptide of the invention.

The invention includes fragments of any of the nucleic acids described herein wherein the fragment retains a biological or structural function by which the full-length nucleic acid is characterized (e.g., an activity, an encoded protein, or a binding capacity). The invention furthermore includes fragments of any of the nucleic acids described herein wherein the fragment has a nucleotide sequence sufficiently (e.g., 50%, 60%, 70%, 80%, 85%, 90%, 95%, 98%, or 99% or greater) identical to the nucleotide sequence of the corresponding full-length nucleic acid that it retains a biological or structural function by which the full-length nucleic acid is characterized (e.g., an activity, an encoded protein, or a binding capacity).

The invention includes fragments of any of the polypeptides described herein wherein the fragment retains a biological or structural function by which the full-length polypeptide is characterized (e.g., an activity or a binding capacity). The invention furthermore includes fragments of any of the polypeptides described herein wherein the fragment has an amino acid sequence sufficiently (e.g., 50%, 60%, 70%, 80%, 85%, 90%, 95%, 98%, or 99% or greater) identical to the amino acid sequence of the corresponding full-length polypeptide that it retains a biological or structural function by which the full-length polypeptide is characterized (e.g., an activity or a binding capacity).

The invention also features nucleic acid molecules which are at least 40% (or 50%, 60%, 70%, 80%, 90%, 95%, or 98%) identical to the nucleotide sequence of

any of SEQ ID NOs: 1, 2, 31, 32, 51, 52, 71, 72, 81, 82, 91, 92, 96, 97, 101, 102, 106, 107, 111, 112, 121, 122, 141, 142, 151, 152, 161, 162, 171, 172, 181, 182, 191, 192, 201, 202, 215, 217, 221, 222, 241, 242, 251, 252, 271, 272, 279, 280, 303, 304, 308, 309, 324, 325, 329, 330, 351, 352, 362, 371, 372, 379, 380, 387, 388, 403, 404, 5 415, 416, 423, 424, 437, and 438, the TANGO 202 nucleotide sequence of the cDNA insert of a clone deposited on April 21, 1999 with the ATCC® as accession no. 207219, the TANGO 202 nucleotide sequence of the cDNA insert of a clone deposited on April 21, 1999 with the ATCC® as accession no. 207221, the TANGO 210 nucleotide sequence of the cDNA insert of a clone deposited on July 29, 1999 10 with the ATCC® as accession no. PTA-438, the INTERCEPT 217 nucleotide sequence of the cDNA insert of a clone deposited on May 28, 1999 with the ATCC® as accession no. PTA-147, the TANGO 229 nucleotide sequence of the cDNA insert of a clone deposited on October 1, 1999 with the ATCC® as accession no. PTA-295, the TANGO 234 nucleotide sequence of the cDNA insert of a clone deposited on 15 April 2, 1999 with the ATCC® as accession no. 207184, the TANGO 265 nucleotide sequence of the cDNA insert of a clone deposited on April 28, 1999 with the ATCC® as accession no. 207228, the TANGO 276 nucleotide sequence of the cDNA insert of a clone deposited on May 28, 1999 with the ATCC® as accession no. PTA-150, the TANGO 286 nucleotide sequence of the cDNA insert of a clone 20 deposited on April 21, 1999 with the ATCC® as accession no. 207220, the INTERCEPT 289 nucleotide sequence of the cDNA insert of a clone deposited on October 1, 1999 with the ATCC® as accession no. PTA-295, the TANGO 292 nucleotide sequence of the cDNA insert of a clone deposited on April 28, 1999 with the ATCC® as accession no. 207230, the TANGO 294 nucleotide sequence of the 25 cDNA insert of a clone deposited on April 21, 1999 with the ATCC® as accession no. 207220, the INTERCEPT 296 nucleotide sequence of the cDNA insert of a clone deposited on April 21, 1999 with the ATCC® as accession no. 207220, the INTERCEPT 297 nucleotide sequence of the cDNA insert of a clone deposited on May 28, 1999 with the ATCC® as accession no. PTA-147, the INTERCEPT 309

nucleotide sequence of the cDNA insert of a clone deposited on January 6, 2000 with the ATCC® as accession no. PTA-1156, the TANGO 331 nucleotide sequence of the cDNA insert of a clone deposited on May 28, 1999 with the ATCC® as accession no. PTA-147, the TANGO 332 nucleotide sequence of the cDNA insert of a clone deposited on May 28, 1999 with the ATCC® as accession no. PTA-151, the TANGO 366 nucleotide sequence of the cDNA insert of a clone deposited on July 23, 1999 with the ATCC® as accession no. PTA-424, the INTERCEPT 394 nucleotide sequence of the cDNA insert of a clone deposited on July 23, 1999 with the ATCC® as accession no. PTA-424, the INTERCEPT 400 nucleotide sequence of the cDNA insert of a clone deposited on July 29, 1999 with the ATCC® as accession no. PTA-438, the TANGO 416 nucleotide sequence of the cDNA insert of a clone deposited on April 26, 1999 with the ATCC® as accession no. PTA-1764, the MANGO 419 nucleotide sequence of the cDNA insert of a clone deposited on January 6, 2000 with the ATCC® as accession no. PTA-1156, the INTERCEPT 429 nucleotide sequence of the cDNA insert of a clone deposited on August 5, 1999 with the ATCC® as accession no. PTA-455, the TANGO 457 nucleotide sequence of the cDNA insert of a clone deposited on October 1, 1999 with the ATCC® as accession no. PTA-817, or a complement thereof. These deposited nucleotide sequences are hereafter individually and collectively referred to as "the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764."

The invention features nucleic acid molecules which include a fragment of at least 15 (25, 40, 60, 80, 100, 150, 200, 250, 300, 350, 400, 450, 500, 600, 700, 800, 900, 1000, 1200, 1400, 1600, 1800, 2000, 2200, 2400, 2600, 2800, 3000, 3500, 4000, 4500, 5000, or more) consecutive nucleotide residues of any of SEQ ID NOs: 1, 2, 31, 32, 51, 52, 71, 72, 81, 82, 91, 92, 96, 97, 101, 102, 106, 107, 111, 112, 121, 122, 141, 142, 151, 152, 161, 162, 171, 172, 181, 182, 191, 192, 201, 202, 215, 217, 221, 222, 241, 242, 251, 252, 271, 272, 279, 280, 303, 304, 308, 309, 324, 325, 329,

330, 351, 352, 362, 371, 372, 379, 380, 387, 388, 403, 404, 415, 416, 423, 424, 437, 438, and the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764, or a complement thereof.

The invention also features nucleic acid molecules which include a nucleotide sequence encoding a protein having an amino acid sequence that is at least 50% (or 60%, 70%, 80%, 90%, 95%, or 98%) identical to the amino acid sequence of any of SEQ ID NOs: 3-8, 33, 35, 38, 53-60, 73-78, 83-85, 93-95, 98-100, 103-105, 108-110, 113-115, 123-131, 143-145, 153-160, 163, 173-175, 183-185, 193-198, 203-214, 216, 223-236, 243-252, 253, 273-278, 281-302, 305-307, 310-315, 326-328, 331-333, 353-358, 363-368, 373-378, 381-386, 389-394, 405-414, 417-422, 425-436, and 439, or the amino acid sequence encoded by the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764 or a complement thereof.

In certain embodiments, the nucleic acid molecules have the nucleotide sequence of any of SEQ ID NOs: 1, 2, 31, 32, 51, 52, 71, 72, 81, 82, 91, 92, 96, 97, 101, 102, 106, 107, 111, 112, 121, 122, 141, 142, 151, 152, 161, 162, 171, 172, 181, 182, 191, 192, 201, 202, 215, 217, 221, 222, 241, 242, 251, 252, 271, 272, 279, 280, 303, 304, 308, 309, 324, 325, 329, 330, 351, 352, 362, 371, 372, 379, 380, 387, 388, 403, 404, 415, 416, 423, 424, 437, 438, and the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764.

Also within the invention are nucleic acid molecules which encode a fragment of a polypeptide having the amino acid sequence of any of SEQ ID NOs: 3-8, 33, 35, 38, 53-60, 73-78, 83-85, 93-95, 98-100, 103-105, 108-110, 113-115, 123-

60, 73-78, 83-85, 93-95, 98-100, 103-105, 108-110, 113-115, 123-131, 143-145, 153-160, 163, 173-175, 183-185, 193-198, 203-214, 216, 223-236, 243-252, 253, 273-278, 281-302, 305-307, 310-315, 326-328, 331-333, 353-358, 363-368, 373-378, 381-386, 389-394, 405-414, 417-422, 425-436, and 439.

5 Also within the invention are isolated polypeptides or proteins which are encoded by a nucleic acid molecule having a nucleotide sequence that is at least about 40%, preferably 50%, 60%, 75%, 85%, or 95% identical the nucleic acid sequence encoding any of SEQ ID NOs: 3-8, 33, 35, 38, 53-60, 73-78, 83-85, 93-95, 98-100, 103-105, 108-110, 113-115, 123-131, 143-145, 153-160, 163, 173-175, 183-
10 185, 193-198, 203-214, 216, 223-236, 243-252, 253, 273-278, 281-302, 305-307, 310-315, 326-328, 331-333, 353-358, 363-368, 373-378, 381-386, 389-394, 405-414, 417-422, 425-436, and 439, and isolated polypeptides or proteins which are encoded by a nucleic acid molecule consisting of the nucleotide sequence which hybridizes under stringent hybridization conditions to a nucleic acid molecule having
15 the nucleotide sequence of any of SEQ ID NOs: 1, 2, 31, 32, 51, 52, 71, 72, 81, 82, 91, 92, 96, 97, 101, 102, 106, 107, 111, 112, 121, 122, 141, 142, 151, 152, 161, 162, 171, 172, 181, 182, 191, 192, 201, 202, 215, 217, 221, 222, 241, 242, 251, 252, 271, 272, 279, 280, 303, 304, 308, 309, 324, 325, 329, 330, 351, 352, 362, 371, 372, 379, 380, 387, 388, 403, 404, 415, 416, 423, 424, 437, 438, and the nucleotide sequence
20 of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764.

 Also within the invention are polypeptides which are naturally occurring allelic variants of a polypeptide that includes the amino acid sequence of any of SEQ
25 ID NOs: 3-8, 33, 35, 38, 53-60, 73-78, 83-85, 93-95, 98-100, 103-105, 108-110, 113-115, 123-131, 143-145, 153-160, 163, 173-175, 183-185, 193-198, 203-214, 216, 223-236, 243-252, 253, 273-278, 281-302, 305-307, 310-315, 326-328, 331-333, 353-358, 363-368, 373-378, 381-386, 389-394, 405-414, 417-422, 425-436, and 439, wherein the polypeptide is encoded by a nucleic acid molecule which hybridizes

under stringent conditions to a nucleic acid molecule having the nucleotide sequence of any of SEQ ID NOs: 1, 2, 31, 32, 51, 52, 71, 72, 81, 82, 91, 92, 96, 97, 101, 102, 106, 107, 111, 112, 121, 122, 141, 142, 151, 152, 161, 162, 171, 172, 181, 182, 191, 192, 201, 202, 215, 217, 221, 222, 241, 242, 251, 252, 271, 272, 279, 280, 303, 304, 308, 309, 324, 325, 329, 330, 351, 352, 362, 371, 372, 379, 380, 387, 388, 403, 404, 415, 416, 423, 424, 437, 438, and the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764, or a complement thereof.

10 The invention also features nucleic acid molecules that hybridize under stringent conditions to a nucleic acid molecule having the nucleotide sequence of any of SEQ ID NOs: 1, 2, 31, 32, 51, 52, 71, 72, 81, 82, 91, 92, 96, 97, 101, 102, 106, 107, 111, 112, 121, 122, 141, 142, 151, 152, 161, 162, 171, 172, 181, 182, 191, 192, 201, 202, 215, 217, 221, 222, 241, 242, 251, 252, 271, 272, 279, 280, 303, 304, 308, 309, 324, 325, 329, 330, 351, 352, 362, 371, 372, 379, 380, 387, 388, 403, 404, 415, 416, 423, 424, 437, 438, and the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764, or a complement thereof. In some embodiments, the isolated nucleic acid molecules encode a cytoplasmic, transmembrane, extracellular, or other domain of a polypeptide of the invention. In other embodiments, the invention provides an isolated nucleic acid molecule which is antisense to the coding strand of a nucleic acid of the invention.

25 Another aspect of the invention provides vectors, e.g., recombinant expression vectors, comprising a nucleic acid molecule of the invention. In another embodiment, the invention provides isolated host cells, e.g., mammalian or non-mammalian cells, containing such a vector or a nucleic acid of the invention. The invention also provides methods for producing a polypeptide of the invention by culturing, in a suitable medium, a host cell of the invention containing a recombinant

expression vector encoding a polypeptide of the invention such that the polypeptide of the invention is produced.

Another aspect of this invention features isolated or recombinant proteins and polypeptides of the invention. Preferred proteins and polypeptides possess at least one biological activity possessed by the corresponding naturally-occurring human polypeptide. An activity, a biological activity, and a functional activity of a polypeptide of the invention refers to an activity exerted by a protein or polypeptide of the invention on a responsive cell as determined in vivo, or in vitro, according to standard techniques. Such activities can be a direct activity, such as an association with or an enzymatic activity exerted on a second protein or an indirect activity, such as a cellular processes mediated by interaction of the protein with a second protein.

The observations that expression of TANGO 416 protein is up-regulated in porcine endothelial cells, that TANGO 416 is a member of the cadherin family of proteins, and that at least one cadherin (designated E-cadherin), which is expressed in endothelial cells, binds to integrin $\alpha E\beta 7$ indicate that TANGO 416 protein can also bind with integrin $\alpha E\beta 7$. Thus, TANGO 416 nucleic acids, proteins, compounds which modulate their activity, expression, or both, and compounds (e.g., antibodies) which bind with TANGO 416 proteins (collectively "TANGO 416-related molecules") can modulate one or more of growth, proliferation, survival, differentiation, activity, morphology, and movement / migration of, for example, cells (e.g. endothelial cells) which normally express TANGO 416 and cells (e.g. certain T cells, eosinophils, mast cells, and other lymphocytes) which normally express integrin $\alpha E\beta 7$.

The ability of TANGO 416 to bind with integrin $\alpha E\beta 7$ indicates that TANGO 416 protein and other TANGO 416-related molecules can be used to modulate the physiological activities associated with integrin $\alpha E\beta 7$ function and to treat disorders to which such physiological activities contribute. TANGO 416 protein can thus be involved in disorders which affect epithelial and lymphocytic tissues. Such disorders include cell proliferation disorders, disorders associated with aberrant epithelial

permeability, auto-, hypo-, and hyper-immune disorders, disorders associated with aberrant binding or adhesion of cells with other cells, and inflammatory disorders. TANGO 416-related molecules can be used to prognosticate, prevent, diagnose, or treat one or more such disorders.

5 The present invention is based, at least in part, on the discovery of cDNA molecules which encode TANGO 457 proteins, which are transmembrane proteins with one or more immunoglobulin domains and which are encoded by sequences expressed in at least, uterus, fetal liver, fetal spleen, and placenta tissues.

 The biological activities of TANGO 457 and modulators thereof include, e.g.,
10 (1) the ability to form, e.g., stabilize, promote, inhibit, or disrupt, protein-protein interactions (e.g., homophilic and/or heterophilic) with proteins in the signaling pathway of the naturally-occurring polypeptide; (2) the ability to bind a ligand of the naturally-occurring polypeptide; and (3) the ability to interact with a TANGO 457 receptor. Other activities include the ability to modulate function, survival,
15 morphology, migration, proliferation and/or differentiation of cells of tissues (e.g., uterus, fetal liver, fetal spleen, and placenta) in which it is expressed.

 TANGO 229, compounds which modulate its activity, expression, or both, and compounds which interact with TANGO 229 can exhibit the ability to affect one or more of growth, proliferation, survival, differentiation, activity, morphology, and
20 movement / migration of, for example, T cells and cells of heart, liver, pancreas, placenta, brain lung, skeletal muscle, kidney, spleen, lymph node, peripheral blood leukocyte, bone marrow, and thymus tissues. TANGO 229 protein can be involved in mediating cell binding and adhesion, including binding / adhesion of cells with other cells, with extracellular matrix, and with foreign materials. TANGO 229
25 protein can thus have a role in disorders associated with aberrant binding of these types. TANGO 229 protein can also be involved in mediating attraction and repulsion of cells and translocation of cells through, past, or along other cells or tissues. TANGO 229 protein can furthermore be involved in transducing signals across the cell membrane.

INTERCEPT 289, compounds which modulate its activity, expression, or both, and compounds which interact with INTERCEPT 289 can exhibit the ability to affect one or more of growth, proliferation, survival, differentiation, activity, morphology, and movement / migration of, for example, lymphocytes such as monocytes and macrophages. INTERCEPT 289 protein can be involved in activating one or more types of macrophages and monocytes, and thus can be involved in one or more immune disorders and other types of disorders mediated by monocytes and macrophages.

INTERCEPT 309, compounds which modulate its activity, expression, or both, and compounds which interact with INTERCEPT 309 modulate one or more of growth, proliferation, survival, differentiation, activity, morphology, and movement / migration of cells of brain, liver, colon, prostate, kidneys, thyroid, and other epithelial and endothelial tissues. INTERCEPT 309 is a claudin-like protein, and can modulate tight-junction regulated intercellular and paracellular diffusion. INTERCEPT 309 also can participate in cell-to-cell adhesive mechanisms that do not necessarily involve tight junction formation. In addition, INTERCEPT 309 can mediate interaction of cells in which it is expressed with Clostridium perfringens enterotoxin, and can thus be involved in disorders mediated by C. perfringens and other pathogens. Furthermore, INTERCEPT 309 is associated with normal and aberrant apoptosis, and thus with disorders associated with aberrant apoptosis.

MANGO 419, compounds which modulate its activity, expression, or both, and compounds which interact with MANGO 419 can modulate one or more of growth, proliferation, survival, differentiation, activity, morphology, and movement / migration of, for example, cells of embryonic and mammary, prostate, and other epithelial and endothelial tissues. MANGO 419 protein can be involved in disorders which affect epithelial and endothelial tissues. Such disorders include cell proliferation disorders, disorders associated with aberrant epithelial / endothelial permeability, and disorders associated with aberrant binding or adhesion of cells with other cells, with extracellular matrix, or with foreign materials.

INTERCEPT 429, compounds which modulate its activity, expression, or both, and compounds which interact with INTERCEPT 429 can modulate one or more of growth, proliferation, survival, differentiation, activity, morphology, and movement / migration of, for example, cells of cardiac muscle, small intestine, and one or more of fetal lung, testis, and B cell tissues. INTERCEPT 429 can be involved in modulating growth, proliferation, survival, differentiation, and activity of cells of these tissues, in both normal and diseased tissues.

TANGO 210, compounds which modulate its activity, expression, or both, and compounds which interact with TANGO 210 exhibit the ability to affect one or more of growth, proliferation, survival, differentiation, activity, morphology, and movement/migration of, for example, human adult kidney, fetal kidney, skin, and bone marrow cells and tissues. TANGO 210 modulates the structure of extracellular matrix within, or in fluid communication with, one or more of these tissues. For example, TANGO 210 exhibits proteinase activity that can enzymatically degrade one or more of the proteinaceous components of extracellular matrix. Thus, TANGO 210-related molecules can be used to prognosticate, prevent, diagnose, or treat disorders relating to aberrant formation or degradation of extracellular matrix. In various embodiments, for example, TANGO 210 is used to prognosticate, prevent, diagnose, or treat kidney, bone marrow, and skin disorders. TANGO 210 can also be used to prognosticate, prevent, diagnose, or treat one or more cancers, including metastatic cancers.

TANGO 366, compounds which modulate its activity, expression, or both, and compounds which interact with TANGO 366 modulate one or more of growth, proliferation, survival, differentiation, activity, morphology, and movement/migration of human fibroblast cells and tissues in which fibroblasts normally or aberrantly occur. TANGO 366 is a cell surface protein-binding protein. TANGO 366 modulates binding of a cell which expresses it with one or more of an extracellular fluid protein, a protein component of the extracellular matrix, a surface protein another cell of the same animal, and a surface protein of a bacterium, fungus, or virus. TANGO 366 is therefore involved in cell-to-cell adhesion, tissue and extracellular matrix invasivity of

cells, infectivity of cells by pathogens such as bacteria and viruses, endocrine signaling processes, tissue developmental and organizational processes, and the like.

INTERCEPT 394, compounds which modulate its activity, expression, or both, and compounds which interact with INTERCEPT 394 modulate one or more of
5 growth, proliferation, survival, differentiation, activity, morphology, and movement/migration of, for example, human adult and fetal kidney cells and tissues. INTERCEPT 394, a transmembrane protein, is involved in modulation of intracellular processes, including modulation that is effected upon binding of a ligand to an extracellular portion of INTERCEPT 394. INTERCEPT 394 protein is thus capable of
10 transmitting signals across a membrane (e.g., from a signal source outside the cell to a molecule within the cell or from a signal source within the cell to a molecule outside the cell), along a membrane (i.e., between two or more molecules on a single side of a membrane), and combinations thereof. INTERCEPT 394 protein is also capable of interacting with other membrane-associated proteins to form complexes, the activity or
15 specificity of which can be affected by association of INTERCEPT 394 therewith.

INTERCEPT 400, compounds which modulate its activity, expression, or both, and compounds which interact with INTERCEPT 400 modulate one or more of growth, proliferation, survival, differentiation, activity, morphology, and movement/migration of, for example, human adult and fetal keratinocytes and brain
20 cells and tissues. INTERCEPT 400 is a transmembrane protein that is involved in modulating interactions between membrane components and cellular cytoskeletons, such as interactions involved in activation of leukocytes, interactions involved in affecting cellular metabolism, interactions involved in cellular growth, and interactions involved in cellular proliferation.

25 INTERCEPT 217 polypeptides, nucleic acids, and modulators thereof exhibit the ability to affect growth, proliferation, survival, differentiation, and activity of human pancreas, skeletal muscle, heart, brain, placenta, lung, liver, and kidney cells. INTERCEPT 217 modulates cellular binding to one or more mediators, modulates activity and release of one or more pancreatic secreted digestive enzymes, and

protects tissue from endogenous digestive enzymes. INTERCEPT 217 polypeptides, nucleic acids, and modulators thereof can be used to prevent, diagnose, or treat disorders relating to aberrant endogenous digestive enzyme activity, inappropriate interaction (or non-interaction) of cells with mediators, inappropriate cellular
5 development and proliferation, inappropriate inflammation, and inappropriate immune responses.

INTERCEPT 297 polypeptides, nucleic acids, and modulators thereof exhibit the ability to affect growth, proliferation, survival, differentiation, and activity of human fetal cells and spleen cells and of (e.g., bacterial or fungal) cells and viruses
10 which infect humans. Furthermore, INTERCEPT 297 modulates organization, structure, and function of biological membranes. INTERCEPT 297 polypeptides, nucleic acids, and modulators thereof can be used to affect development and persistence of atherogenesis and arteriosclerosis, for example, or to modulate transmembrane transport processes such as ion transport across neuronal and muscle
15 cell membranes.

TANGO 276 polypeptides, nucleic acids, and modulators thereof modulate growth, proliferation, survival, differentiation, and activity of human heart, placenta, brain, lung, liver, skin, kidney, pancreas, spleen, and fetal tissues. TANGO 276 guides neuronal growth and development and modulates growth, homeostasis, and
20 regeneration of other epithelial tissues. TANGO 276 is a secreted protein which mediates cellular interaction with cells, molecules, and structures (e.g., extracellular matrix) in the extracellular environment. TANGO 276 is involved in growth, organization, migration, and adhesion of tissues and the cells which constitute those tissues. Furthermore, TANGO 276 modulates growth, proliferation, survival,
25 differentiation, and activity of neuronal cells and immune system cells.

TANGO 292 polypeptides, nucleic acids, and modulators thereof modulate growth, proliferation, survival, differentiation, and activity of human keratinocytes, including embryonic keratinocytes. TANGO 292, a transmembrane protein, is also involved in binding and uptake of calcium and other metal ions, and in responses of

cells which express it to the presence and uptake of such ions. TANGO 292 polypeptides, nucleic acids, and modulators can be used to prevent, diagnose, and treat disorders involving one or more of bone uptake, maintenance, and deposition, formation, maintenance, and repair of cartilage and skin, formation and maintenance of
5 extracellular matrices, movement of cells through extracellular matrices, coagulation and dissolution of blood components, and deposition of materials in and on arterial walls.

TANGO 331 polypeptides, nucleic acids, and modulators thereof modulate growth, proliferation, survival, differentiation, and activity of human fetal, lung,
10 spleen, and thymus cells and tissues. As described herein, TANGO 331 is involved in physiological activities such as maintenance of epithelia, carcinogenesis, modulation and storage of protein factors and metals, lactation, and infant nutrition. TANGO 331 also modulates cellular binding and uptake of cytokines, growth factors, and metal ions.

15 TANGO 332 polypeptides, nucleic acids, and modulators thereof modulate growth, proliferation, survival, differentiation, and activity of human brain and other tissues. As described herein, TANGO 332 is involved in modulating establishment and maintenance of neural connections, cell-to-cell adhesion, tissue and extracellular matrix invasivity, and the like.

20 TANGO 202 exhibits the ability to affect growth, proliferation, survival, differentiation, and activity of human hematopoietic cells (e.g., bone marrow stromal cells) and fetal cells. TANGO 202 modulates cellular binding to one or more mediators, modulates proteolytic activity in vivo, modulates developmental processes, and modulates cell growth, proliferation, survival, differentiation, and activity.

25 TANGO 234 exhibits the ability to affect growth, proliferation, survival, differentiation, and activity of human lung, hematopoietic, and fetal cells and of (e.g., bacterial or fungal) cells and viruses which infect humans. TANGO 234 modulates growth, proliferation, survival, differentiation, and activity of gamma delta T cells, for example. Furthermore, TANGO 234 modulates cholesterol deposition on human

arterial walls, and is involved in uptake and metabolism of low density lipoprotein and regulation of serum cholesterol levels.

5 TANGO 265 modulates growth and regeneration of neuronal and epithelial tissues, and guides neuronal axon development. TANGO 265 is a transmembrane protein which mediates cellular interaction with cells, molecules and structures (e.g., extracellular matrix) in the extracellular environment. TANGO 265 is involved in growth, organization, and adhesion of tissues and the cells which constitute those tissues. Furthermore, TANGO 265 modulates growth, proliferation, survival, differentiation, and activity of neuronal cells and immune system cells.

10 TANGO 286 protein is involved in lipid-binding physiological processes such as lipid transport, metabolism, serum lipid particle regulation, host anti-microbial defensive mechanisms, and the like.

15 TANGO 294 protein is involved in facilitating absorption and metabolism of fat. Disorders which can be modulated by TANGO 294 proteins, nucleic acids, and compounds that interact with them include, for example, inadequate expression of gastric/pancreatic lipase, cystic fibrosis, exocrine pancreatic insufficiency, medical treatments which alter fat absorption, and obesity.

20 INTERCEPT 296 protein is involved in physiological processes related to disorders of the human lung and esophagus. Disorders which can be modulated by INTERCEPT 296 proteins, nucleic acids, and compounds that interact with them include, for example, various cancers, bronchitis, cystic fibrosis, respiratory infections (e.g., influenza, bronchiolitis, pneumonia, and tuberculosis), asthma, emphysema, chronic bronchitis, bronchiectasis, pulmonary edema, pleural effusion, pulmonary embolus, adult and infant respiratory distress syndromes, heartburn, and gastric
25 esophageal reflux disease.

In one embodiment, a polypeptide of the invention has an amino acid sequence sufficiently identical to a polypeptide of the invention or to an identified domain thereof. As used herein, the term "sufficiently identical" refers to a first amino acid or nucleotide sequence which contains a sufficient or minimum number

of identical or equivalent (e.g., with a similar side chain) amino acid residues or nucleotides to a second amino acid or nucleotide sequence such that the first and second amino acid or nucleotide sequences have a common domain and/or common functional activity. For example, amino acid or nucleotide sequences which contain
5 a common domain having about 65% identity, preferably 75% identity, more preferably 85%, 95%, or 98% identity are defined herein as sufficiently identical.

In one embodiment, the isolated polypeptide of the invention lacks both a transmembrane and a cytoplasmic domain. In another embodiment, the polypeptide lacks both a transmembrane domain and a cytoplasmic domain and is soluble under
10 physiological conditions.

The polypeptides of the present invention, or biologically active portions thereof, can be operably linked with a heterologous amino acid sequence to form fusion proteins. The invention further features antibody substances that specifically bind a polypeptide of the invention, such as monoclonal or polyclonal antibodies,
15 antibody fragments, and single-chain antibodies. In addition, the polypeptides of the invention or biologically active portions thereof can be incorporated into pharmaceutical compositions, which optionally include pharmaceutically acceptable carriers. These antibody substances can be made, for example, by providing the polypeptide of the invention to an immunocompetent vertebrate and thereafter
20 harvesting blood or serum from the vertebrate.

In another aspect, the present invention provides methods for detecting the presence of the activity or expression of a polypeptide of the invention in a biological sample by contacting the biological sample with an agent capable of detecting an indicator of activity such that the presence of activity is detected in the
25 biological sample.

In another aspect, the invention provides methods for modulating activity of a polypeptide of the invention comprising contacting a cell with an agent that modulates (inhibits or enhances) the activity or expression of a polypeptide of the invention such that activity or expression in the cell is modulated. In one

embodiment, the agent is an antibody that specifically binds with a polypeptide of the invention.

In another embodiment, the agent modulates expression of a polypeptide of the invention by modulating transcription, splicing, or translation of an mRNA
5 encoding a polypeptide of the invention. In yet another embodiment, the agent is a nucleic acid molecule having a nucleotide sequence that is antisense with respect to the coding strand of an mRNA encoding a polypeptide of the invention.

The present invention also provides methods of treating a subject having a disorder characterized by aberrant activity of a polypeptide of the invention or
10 aberrant expression of a nucleic acid of the invention by administering an agent which is a modulator of the activity of a polypeptide of the invention or a modulator of the expression of a nucleic acid of the invention to the subject. In one embodiment, the modulator is a protein of the invention. In another embodiment, the modulator is a nucleic acid of the invention. In other embodiments, the modulator is
15 a peptide, peptidomimetic, or other small molecule. In yet another embodiment, the modulator is an antibody.

The present invention also provides diagnostic assays for identifying the presence or absence of a genetic lesion or mutation characterized by at least one of:
(i) aberrant modification or mutation of a gene encoding a polypeptide of the
20 invention, (ii) mis-regulation of a gene encoding a polypeptide of the invention, and (iii) aberrant post-translational modification of a polypeptide of the invention wherein a wild-type form of the gene encodes a polypeptide having the activity of the polypeptide of the invention.

In another aspect, the invention provides a method for identifying a
25 compound that binds with or modulates the activity of a polypeptide of the invention. In general, such methods entail measuring a biological activity of the polypeptide in the presence and absence of a test compound and identifying those compounds which bind with or alter the activity of the polypeptide.

The invention also features methods for identifying a compound which modulates the expression of a polypeptide or nucleic acid of the invention by measuring the expression of the polypeptide or nucleic acid in the presence and absence of the compound.

5 Other features and advantages of the invention will be apparent from the following detailed description and claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 comprises Figures 1A through 1I. The nucleotide sequence (SEQ ID
10 NO: 1) of a cDNA encoding the human TANGO 416 protein described herein is listed in Figures 1A through 1I. The open reading frame (ORF; residues 376 to 3780; SEQ ID NO: 2) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 3) of human TANGO 416 is listed.

Figure 2 comprises Figures 2A through 2I. The nucleotide sequence (SEQ ID
15 NO: 31) of a cDNA encoding the human TANGO 416 protein described herein is listed in Figures 2A through 2I. The open reading frame (ORF; residues 376 to 3777; SEQ ID NO: 32) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 33) of human TANGO 416 is listed.

Figure 3 is a hydrophobicity plot of the embodiment of human TANGO 416
20 protein listed in Figure 1. In the hydrophobicity plots disclosed herein, the locations of cysteine residues ("Cys") and potential N-glycosylation sites ("Ngly") are indicated by vertical bars and the predicted extracellular ("out"), intracellular ("ins"), or transmembrane ("TM") portions of the protein backbone are indicated by a horizontal bar. Relatively hydrophobic regions of the protein are above the dashed horizontal
25 line, and relatively hydrophilic regions of the protein are below the dashed horizontal line.

Figure 4 is an alignment of a portion of the TANGO 416 cDNA sequence ("T416"; residues 1651-4000 of SEQ ID NO: 1) with a human testis cDNA clone having GenBank accession number AL137471 ("AL137471"; SEQ ID NO: 40). This

alignment indicates that the two nucleotide sequences are about 98.6% identical over the overlapping region. The alignment was made using the ALIGN software (BLOSUM62 scoring matrix, gap opening penalty 12, gap extension penalty 4, frameshift gap penalty 5). In the alignments in this disclosure, similar residues are indicated by ".", and identical residues are indicated by ":" or "|".

Figure 5 is an alignment of a portion of the TANGO 416 ORF nucleotide sequence ("T416"; residues 1-3405 of SEQ ID NO: 2) with the ORF nucleotide sequence ("m-PC"; SEQ ID NO: 41) of murine protocadherin (sometimes designated vascular endothelial cadherin-2 or mVE-cad-2). This alignment indicates that the two nucleotide sequences are about 55.4% identical over the overlapping region. The alignment was made using the ALIGN software (BLOSUM62 scoring matrix, gap opening penalty 12, gap extension penalty 4, frameshift gap penalty 5).

Figure 6 is an alignment of a portion of the TANGO 416 protein amino acid sequence ("T416"; residues 1-1135 of SEQ ID NO: 3) with the amino acid sequence ("m-PC"; SEQ ID NO: 42) of murine protocadherin. This alignment indicates that the two amino acid sequences are about 32.8% identical over the overlapping region. The alignment was made using the ALIGN software (BLOSUM62 scoring matrix, gap opening penalty 12, gap extension penalty 4).

Figures 7A through 7D depict a cDNA sequence of human TANGO 457 (SEQ ID NO: 51) and the predicted human TANGO 457 amino acid sequence encoded by the sequence (SEQ ID NO: 53). The open reading frame of TANGO 457, comprises nucleotide 149 to nucleotide 1243 of SEQ ID NO: 51 (SEQ ID NO: 52).

Figure 8 depicts a hydrophobicity plot of human TANGO 457.

Figures 9A through 9D depict a local alignment of the nucleic acid of human TANGO 457 shown in SEQ ID NO: 51 and a portion of the nucleotide sequence of human chromosome 11p14.3 PAC clone pDJ239b22, from nucleic acids 121077 to 122478 (SEQ ID NO: 61; accession number AC003969). In the alignment, the TANGO 457 sequence is the top strand, and the 11p14.3 PAC clone pDJ239b22 sequences is on the bottom. The alignment shows that there is 100% nucleotide

sequence identity between the TANGO 457 sequence of SEQ ID NO: 51 and human chromosome 11p14.3 PAC clone pDJ239b22, from nucleotides 908 to 2305 of TANGO 457. This alignment was performed using the ALIGN alignment program with a PAM120 scoring matrix, a gap length penalty of 12, and a gap penalty of 4.

- 5 Figure 10 comprises Figures 10A through 10G. The nucleotide sequence (SEQ ID NO: 71) of a cDNA encoding the human TANGO 229 protein described herein is listed in Figures 10A through 10F. The open reading frame (ORF; residues 72 to 2216; SEQ ID NO: 72) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 73) of human TANGO 229 is listed.
- 10 Figure 10G is a hydrophobicity plot of one embodiment of human TANGO 229 protein.

Figure 11 comprises Figures 11A through 11Z-6.

- The nucleotide sequence (SEQ ID NO: 81) of a cDNA encoding form 1a of the human INTERCEPT 289 protein described herein is listed in Figures 11A
- 15 through 11C. The ORF (residues 179 to 742; SEQ ID NO: 82) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 83) of form 1a of human INTERCEPT 289 is listed.

- The nucleotide sequence (SEQ ID NO: 91) of a cDNA encoding form 1b of human INTERCEPT 289 protein described herein is listed in Figures 11D through
- 20 11G. The ORF (residues 179 to 712; SEQ ID NO: 92) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 93) of form 1b of human INTERCEPT 289 is listed.

- The nucleotide sequence (SEQ ID NO: 96) of a cDNA encoding form 2a of human INTERCEPT 289 protein described herein is listed in Figures 11H through
- 25 11K. The ORF (residues 162 to 656; SEQ ID NO: 97) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 98) of form 2a of human INTERCEPT 289 is listed.

 The nucleotide sequence (SEQ ID NO: 101) of a cDNA encoding form 2b of human INTERCEPT 289 protein described herein is listed in Figures 11L through

11O. The ORF (residues 162 to 626; SEQ ID NO: 102) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 103) of form 2b of human INTERCEPT 289 is listed.

5 The nucleotide sequence (SEQ ID NO: 106) of a cDNA encoding form 3a of human INTERCEPT 289 protein described herein is listed in Figures 11P through 11S. The ORF (residues 162 to 596; SEQ ID NO: 107) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 108) of form 3a of human INTERCEPT 289 is listed.

10 The nucleotide sequence (SEQ ID NO: 111) of a cDNA encoding form 3b of human INTERCEPT 289 protein described herein is listed in Figures 11T through 11V. The ORF (residues 162 to 566; SEQ ID NO: 112) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 113) of form 3b of human INTERCEPT 289 is listed.

15 Figure 11W is an alignment, made using the Wisconsin™ BestFit software (Smith and Waterman, (1981) Adv. Appl. Math. 2:482-489; BLOSUM62 scoring matrix, gap opening penalty 10 / gap extension penalty 10) of the amino acid sequences of murine myeloid DNAX accessory protein associated lectin-1 ("M"; MDL-1; SEQ ID NO: 88), murine INTERCEPT 289 ("R"; SEQ ID NO: 163), human MDL-1 ("H"; SEQ ID NO: 86), form 1a of INTERCEPT 289 ("A"; SEQ ID NO: 20 83), form 1b of INTERCEPT 289 ("B"; SEQ ID NO: 93), form 2a of INTERCEPT 289 ("C"; SEQ ID NO: 98), form 2b of INTERCEPT 289 ("D"; SEQ ID NO: 103), form 3a of INTERCEPT 289 ("E"; SEQ ID NO: 108), and form 3b of INTERCEPT 289 ("F"; SEQ ID NO: 113).

25 Figures 11X-6 through 11X-14 is an alignment (made using the Wisconsin™ BestFit software; Smith and Waterman, (1981) Adv. Appl. Math. 2:482-489; gap opening penalty 10 / gap extension penalty 10), of the nucleotide sequences of cDNA molecules encoding form 1a of INTERCEPT 289 ("A"; SEQ ID NO: 81), form 1b of INTERCEPT 289 ("B"; SEQ ID NO: 91), form 2a of INTERCEPT 289 ("C"; SEQ ID NO: 96), form 2b of INTERCEPT 289 ("D"; SEQ ID NO: 101), form

3a of INTERCEPT 289 ("E"; SEQ ID NO: 106), and form 3b of INTERCEPT 289 ("F"; SEQ ID NO: 111).

Figures 11Y-1 through 11Y-6 is a series of hydrophobicity plots for individual forms of human INTERCEPT 289 protein. The plot corresponding to form 1a is shown in Figure 11Y-1. The plot corresponding to form 1b is shown in Figure 11Y-2. The plot corresponding to form 2a is shown in Figure 11Y-3. The plot corresponding to form 2b is shown in Figure 11Y-4. The plot corresponding to form 3a is shown in Figure 11Y-5. The plot corresponding to form 3b is shown in Figure 11Y-6.

The nucleotide sequence (SEQ ID NO: 161) of a cDNA encoding murine INTERCEPT 289 protein described herein is listed in Figures 11Z-1 through 11Z-3. The ORF (residues 198 to 767; SEQ ID NO: 162) of the cDNA is indicated by nucleotide triplets, beneath which the amino acid sequence (SEQ ID NO: 163) of murine INTERCEPT 289 is listed. Figures 11Z-4 and 11Z-5 are a manual alignment of the nucleotide sequences of murine INTERCEPT 289 ORF ("MI289"; SEQ ID NO: 162) and the ORF of form 1a of human INTERCEPT 289 ("HI289"; SEQ ID NO: 82). Figure 11Z-6 is a hydrophobicity plot for murine INTERCEPT 289 protein.

Figure 12 comprises Figures 12A through 12T. The nucleotide sequence (SEQ ID NO: 121) of a cDNA encoding the human INTERCEPT 309 protein described herein is listed in Figures 12A through 12C. The ORF (residues 2 to 646; SEQ ID NO: 122) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 123) of human INTERCEPT 309 is listed. Figure 12D is a hydrophobicity plot of human INTERCEPT 309 protein. An alignment (made using the ALIGN software; pam120.mat scoring matrix, gap opening penalty = 12, gap extension penalty = 4) of the nucleotide sequences of a cDNA clone ("DKFZ"; SEQ ID NO: 134; GenBank accession no. AL049977) obtained from human fetal brain tissue and INTERCEPT 309 cDNA ("I309"; SEQ ID NO: 121) is shown in Figures 12E through 12K. An alignment (made using the

ALIGN software; pam120.mat scoring matrix, gap opening penalty = 12, gap extension penalty = 4) of the nucleotide sequences of the cDNA encoding human INTERCEPT 309 ("I309"; SEQ ID NO: 121) and a portion of a cDNA encoding murine claudin-8 protein ("CLAUD8"; SEQ ID NO: 132) is shown in Figures 12L through 12R. An alignment (made using the ALIGN software; pam120.mat scoring matrix, gap opening penalty = 12, gap extension penalty = 4) of the amino acid sequences of human INTERCEPT 309 protein ("I309"; SEQ ID NO: 123) and murine claudin-8 protein ("CLAUD8"; SEQ ID NO: 133) is shown in Figure 12S. A manual alignment of individual alignments (made using the Wisconsin™ BestFit software; Smith and Waterman (1981) Adv. Appl. Math. 2:482-489; blosum62 scoring matrix, gap opening penalty 10 / gap extension penalty 10) of the amino acid sequences of human INTERCEPT 309 protein ("I309"; SEQ ID NO: 123) with each of human *Clostridium perfringens* enterotoxin receptor ("hCPE"; SEQ ID NO: 135), murine *C. perfringens* enterotoxin receptor ("mCPE"; SEQ ID NO: 136), and a protein encoded by a cDNA recovered from regressing rat ventral prostate tissue ("rRPV"; SEQ ID NO: 137) is shown in Figure 12T.

Figure 13 comprises Figures 13A and 13B. The nucleotide sequence (SEQ ID NO: 141) of a cDNA encoding the human MANGO 419 protein described herein is listed in Figure 13A. The ORF (residues 84 to 323; SEQ ID NO: 142) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 143) of human MANGO 419 is listed. Figure 13B is a hydrophobicity plot of human MANGO 419 protein.

Figure 14 comprises Figures 14A and 14B. The nucleotide sequence (SEQ ID NO: 151) of a cDNA encoding the human INTERCEPT 429 protein described herein is listed in Figure 14A. The ORF (residues 95 to 439; SEQ ID NO: 152) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 153) of human INTERCEPT 429 is listed. Figure 14B is a hydrophobicity plot of human INTERCEPT 429 protein.

Figure 15 comprises Figures 15A through 15Y. The nucleotide sequence (SEQ ID NO: 171) of a cDNA encoding the human TANGO 210 protein described herein is listed in Figures 15A, 15B, 15C, and 15D. The open reading frame (ORF; residues 45 to 1583; SEQ ID NO: 172) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 173) of human TANGO 210 is listed. Figure 15E is a hydrophobicity plot of human TANGO 210 protein (the conformation of the alternative form of TANGO 210 protein, wherein the carboxyl terminal portion comprises a transmembrane domain, is shown here). The nucleotide sequence (SEQ ID NO: 181) of a cDNA encoding the murine TANGO 210 protein described herein is listed in Figures 15F, 15G, 15H, and 15I. The ORF (residues 22 to 927 and 1280 to 1906; collectively, SEQ ID NO: 182) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 183) of murine TANGO 210 is listed. Figure 15J is a hydrophobicity plot of murine TANGO 210 protein. An alignment of the amino acid sequences of human TANGO 210 protein (SEQ ID NO: 173) and murine TANGO 210 protein (SEQ ID NO: 183) amino acid sequences is shown in Figures 15K and 15L, wherein identical amino acid residues are indicated by ":" and similar amino acid residues are indicated by ".". An alignment of the nucleotide sequences of the human (SEQ ID NO: 171) and murine (SEQ ID NO: 181) cDNAs encoding TANGO 210 protein is shown in Figures 15M through 15U. Figures 15V and 15W are an alignment of the amino acid sequences of human TANGO 210 protein ("210"; SEQ ID NO: 173) and human matrix metalloproteinase-8 (MMP-8; "MMP-8"; SEQ ID NO: 176). An alignment of the nucleotide sequences of the open reading frame (ORF) encoding human TANGO 210 ("210"; SEQ ID NO: 172) and the ORF encoding human MMP-8 (SEQ ID NO: 177) is shown in Figures 15X-1 through 15X-6. Figure 15Y is a graph which depicts expression of TANGO 210 mRNA in selected human tissue and cell types, relative to TANGO 210 expression in the human fetal heart tissue.

Figure 16 comprises Figures 16A through 16E. The nucleotide sequence (SEQ ID NO: 191) of a cDNA encoding the human TANGO 366 protein described herein is

listed in Figures 16A through 16D. The ORF (residues 86 to 1144; SEQ ID NO: 192) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 193) of human TANGO 366 is listed. Figure 16E is a hydrophobicity plot of human TANGO 366 protein.

5 Figure 17 comprises Figures 17A through 17M. The nucleotide sequence (SEQ ID NO: 201) of a cDNA encoding the human INTERCEPT 394 protein described herein is listed in Figures 17A through 17F. The ORF (residues 320 to 2653; SEQ ID NO: 202) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 203) of human INTERCEPT 394 is listed. Figure 17G is a
10 hydrophobicity plot of human INTERCEPT 394 protein. The nucleotide sequence (SEQ ID NO: 201) of a cDNA encoding the human INTERCEPT 394 protein described herein is listed in Figures 17H through 17M. The alternative ORF (residues 120 to 2567; SEQ ID NO: 215) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 216) of this alternative form of human
15 INTERCEPT 394 protein is listed.

 Figure 18 comprises Figures 18A through 18R. The nucleotide sequence (SEQ ID NO: 221) of a cDNA encoding the human INTERCEPT 400 protein described herein is listed in Figures 18A through 18C. The ORF (residues 206 to 1000; SEQ ID NO: 222) of the cDNA is indicated by nucleotide triplets, above which the amino acid
20 sequence (SEQ ID NO: 223) of human INTERCEPT 400 is listed. Figure 18D is a hydrophobicity plot of human INTERCEPT 400 protein. The nucleotide sequence (SEQ ID NO: 241) of a cDNA encoding the murine INTERCEPT 400 protein described herein is listed in Figures 18E and 18F. The ORF (residues 3 to 524; SEQ ID NO: 242) of the cDNA is indicated by nucleotide triplets, above which the amino
25 acid sequence (SEQ ID NO: 243) of murine INTERCEPT 400 is listed. Figure 18G is a hydrophobicity plot of murine INTERCEPT 400 protein. An alignment of the amino acid sequences of human INTERCEPT 400 protein (SEQ ID NO: 223) and murine INTERCEPT 400 protein (SEQ ID NO: 243) amino acid sequences is shown in Figure 18H. An alignment of the nucleotide sequences of the human (SEQ ID NO: 222) and

murine (SEQ ID NO: 242) ORFs encoding INTERCEPT 400 protein is shown in Figures 18I through 18K. Figure 18L is an alignment of the amino acid sequences of human INTERCEPT 400 protein ("I400"; SEQ ID NO: 223) and murine Cig30 protein ("CIG30"; SEQ ID NO: 239). An alignment of the nucleotide sequences of the ORFs encoding human INTERCEPT 400 protein ("I400"; SEQ ID NO: 222) and the ORF encoding murine Cig30 ("CIG30"; SEQ ID NO: 238) is shown in Figures 18M through 18O. The nucleotide sequence (SEQ ID NO: 251) of a cDNA encoding the rat INTERCEPT 400 protein described herein is listed in Figures 18P and 18Q. The ORF (residues 1 to 432; SEQ ID NO: 252) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 253) of rat INTERCEPT 400 is listed. Figure 18R is an alignment of the amino acid sequences of human (SEQ ID NO: 223), murine (SEQ ID NO: 243), and rat (SEQ ID NO: 253) INTERCEPT 400 proteins.

Figure 19 comprises Figures 19A through 19M. The nucleotide sequence (SEQ ID NO: 271) of a cDNA encoding the human INTERCEPT 217 protein described herein is listed in Figures 19A through 19E. The open reading frame (ORF; residues 215 to 1579; SEQ ID NO: 272) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 273) of human INTERCEPT 217 is listed. Figure 19F is a hydrophobicity plot of human INTERCEPT 217 protein. An alignment of the amino acid sequences of human INTERCEPT 217 protein ("H"; SEQ ID NO: 273) and porcine ribonuclease inhibitor protein ("P"; SwissProt Accession number P10775; SEQ ID NO: 334) is shown in Figures 19G and 19H. These alignments were made using the ALIGN software {Myers and Miller (1989) CABIOS, ver. 2.0}; pam120.mat scoring matrix; gap opening penalty = 12, gap extension penalty = 4). The nucleotide sequence (SEQ ID NO: 362) of an ORF encoding the murine INTERCEPT 217 protein described herein is listed in Figures 19I through 19K. The ORF (residues 1 to 960; SEQ ID NO: 362) is indicated by nucleotide triplets, beneath which the amino acid sequence (SEQ ID NO: 363) of murine INTERCEPT 217 is listed. Figure 19L is a hydrophobicity plot of murine INTERCEPT 217 protein. An

alignment of the amino acid sequences of human INTERCEPT 217 protein ("H"; SEQ ID NO: 273) and murine INTERCEPT 217 protein ("M"; SEQ ID NO: 363) is shown in Figure 1M. These alignments were made using the BESTFIT software (BLOSUM62 scoring matrix, gap opening penalty = 12, frameshift gap penalty = 5, gap extension penalty = 4).

Figure 20 comprises Figures 20A through 20D. The nucleotide sequence (SEQ ID NO: 279) of a cDNA encoding the human INTERCEPT 297 protein described herein is listed in Figures 20A, 20B, and 20C. The open reading frame (ORF; residues 40 to 1152; SEQ ID NO: 280) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 281) of human INTERCEPT 297 is listed. Figure 20D is a hydrophobicity plot of human INTERCEPT 297 protein.

Figure 21 comprises Figures 21A through 21R. The nucleotide sequence (SEQ ID NO: 303) of a cDNA encoding the human TANGO 276 protein described herein is listed in Figures 21A to 21D. The ORF (residues 58 to 786; SEQ ID NO: 304) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 305) of human TANGO 276 is listed. Figure 21E is a hydrophobicity plot of TANGO 276 protein. An alignment of the amino acid sequences of human TANGO 276 protein ("H"; SEQ ID NO: 305) and murine protein M-Sema-F ("M"; SEQ ID NO: 335) is shown in Figures 21F to 21H. In Figures 21I through 21R, an alignment of the nucleotide sequences of the cDNA encoding human TANGO 276 protein ("H"; SEQ ID NO: 303) and the nucleotide sequences of the cDNA encoding murine protein M-Sema-F ("M"; SEQ ID NO: 66) is shown. These alignments were made using the ALIGN software {Myers and Miller (1989) CABIOS, ver. 2.0}; pam120.mat scoring matrix; gap opening penalty = 12, gap extension penalty = 4).

Figure 22 comprises Figures 22A through 22M. The nucleotide sequence (SEQ ID NO: 308) of a cDNA encoding the human TANGO 292 protein described herein is listed in Figures 22A to 22C. The ORF (residues 205 to 882; SEQ ID NO: 309) of the cDNA is indicated by nucleotide triplets, beneath which the amino acid sequence (SEQ ID NO: 310) of human TANGO 292 is listed. Figure 22D is a hydrophobicity plot of

human TANGO 292 protein. The nucleotide sequence (SEQ ID NO: 351) of a cDNA encoding the gerbil TANGO 292 protein described herein is listed in Figures 22E to 22H. The ORF (residues 89 to 763; SEQ ID NO: 352) of the cDNA is indicated by nucleotide triplets, below which the amino acid sequence (SEQ ID NO: 353) of gerbil
5 TANGO 292 is listed. Figures 22I to 22K are an alignment of the nucleotide sequences of the ORF encoding human TANGO 292 protein ("H"; SEQ ID NO: 308) and the nucleotide sequence of the ORF encoding gerbil TANGO 292 protein ("G"; SEQ ID NO: 351), made using the ALIGN software {Myers and Miller (1989) CABIOS, ver. 2.0}; pam120.mat scoring matrix; gap opening penalty = 12, gap
10 extension penalty = 4). Figure 22L is an alignment of the human (H) and gerbil (G) TANGO 292 amino acid sequences, made using the same software and parameters. Figure 22M is a hydrophobicity plot of gerbil TANGO 292 protein.

Figure 23 comprises Figures 23A through 23J. The nucleotide sequence (SEQ ID NO: 324) of a cDNA encoding the human TANGO 331 protein described herein is
15 listed in Figures 23A, 23B, and 23C. The ORF (residues 114 to 1172; SEQ ID NO: 325) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 326) of human TANGO 331 is listed. Figure 23D is a hydrophobicity plot of TANGO 331 protein. An alignment of the amino acid sequences of human TANGO 331 protein ("H"; SEQ ID NO: 326) and Chinese
20 hamster protein HT ("C"; SEQ ID NO: 339; GenBank Accession No. U48852) is shown in Figure 23E. In Figures 23F through 23J, an alignment of the nucleotide sequences of the cDNA encoding human TANGO 331 protein ("H"; SEQ ID NO: 324) and the nucleotide sequence of the cDNA encoding Chinese hamster protein HT ("C"; SEQ ID NO: 340) is shown. These alignments were made using the ALIGN software
25 {Myers and Miller (1989) CABIOS, ver. 2.0}; pam120.mat scoring matrix; gap opening penalty = 12, gap extension penalty = 4).

Figure 24 comprises Figures 24A through 24U. The nucleotide sequence (SEQ ID NO: 329) of a cDNA encoding the human TANGO 332 protein described herein is listed in Figures 24A through 24E. The ORF (residues 173 to 2185; SEQ ID NO: 330)

of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 331) of human TANGO 332 protein is listed. Figure 24F is a hydrophobicity plot of TANGO 332 protein. An alignment of the amino acid sequences of TANGO 332 protein ("332"; SEQ ID NO: 331) and BEF protein ("BEF"; SEQ ID NO: 341) is shown in Figures 24G and 24H. An alignment of the amino acid sequences of human TANGO 332 protein ("H"; SEQ ID NO: 331) and murine brevidin protein ("M"; SEQ ID NO: 342) is shown in Figures 24I to 24K. In Figures 24L through 24U, an alignment of the nucleotide sequences of the cDNA encoding human TANGO 332 protein ("H"; SEQ ID NO: 330) and the nucleotide sequence of the cDNA encoding murine brevidin protein ("M"; SEQ ID NO: 343) is shown. These alignments were made using the ALIGN software {Myers and Miller (1989) CABIOS, ver. 2.0}; pam120.mat scoring matrix; gap opening penalty = 12, gap extension penalty = 4).

Figure 25 comprises Figures 25A to 25M. The nucleotide sequence (SEQ ID NO: 371) of a cDNA encoding the human TANGO 202 protein described herein is listed in Figures 25A to 25D. The open reading frame (ORF; residues 34 to 1458; SEQ ID NO: 372) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 373) of human TANGO 202 is listed. The nucleotide sequence (SEQ ID NO: 437) of a cDNA encoding the murine TANGO 202 protein described herein is listed in Figures 25E to 25I. The ORF (residues 81 to 1490; SEQ ID NO: 438) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 439) of murine TANGO 202 is listed. An alignment of the amino acid sequences of human ("Hum."; SEQ ID NO: 373) and murine ("Mur."; SEQ ID NO: 439) TANGO 202 protein is shown in Figures 25J and 25K. Figure 25L is a hydrophobicity plot of human TANGO 202 protein. Figure 25M is a hydrophobicity plot of murine TANGO 202 protein.

Figure 26 comprises Figures 26A to 26Q-19. The nucleotide sequence (SEQ ID NO: 379) of a cDNA encoding the human TANGO 234 protein described herein is listed in Figures 26A to 26I. The ORF (residues 28 to 4386; SEQ ID NO: 380) of the

cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 381) of human TANGO 234 is listed. Figure 26J is a hydrophobicity plot of human TANGO 234 protein. An alignment of the amino acid sequences of human TANGO 234 ("Hum"; SEQ ID NO: 381) and bovine WC1 ("WC1"; SEQ ID NO: 448) proteins is shown in Figures 26K to 26P. An alignment of the nucleotide sequences of an ORF encoding human TANGO 234 ("Hum"; SEQ ID NO: 380) and an ORF encoding bovine WC1 ("WC1"; SEQ ID NO: 449) proteins is shown in Figures 26Q-1 to 26Q-19.

Figure 27 comprises Figures 27A to 27U. The nucleotide sequence (SEQ ID NO: 387) of a cDNA encoding the human TANGO 265 protein described herein is listed in Figures 27A to 27E. The ORF (residues 32 to 2314; SEQ ID NO: 388) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 389) of human TANGO 265 is listed. An alignment of the amino acid sequences of human TANGO 265 protein ("Hum."; SEQ ID NO: 389) and murine semaphorin B protein ("Mur."; SEQ ID NO: 440; GenBank Accession No. X85991) is shown in Figures 27F to 27H. In Figures 27I to 27T, an alignment of the nucleotide sequences of the cDNA encoding human TANGO 265 protein ("Hum."; SEQ ID NO: 387) and the nucleotide sequences of the cDNA encoding murine semaphorin B protein ("Mur."; SEQ ID NO: 441; GenBank Accession No. X85991) is shown. Figure 27U is a hydrophobicity plot of TANGO 265 protein.

Figure 28 comprises Figures 28A to 28I. The nucleotide sequence (SEQ ID NO: 403) of a cDNA encoding the human TANGO 286 protein described herein is listed in Figures 28A to 28D. The ORF (residues 133 to 1497; SEQ ID NO: 404) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 405) of human TANGO 286 is listed. Figure 28E is a hydrophobicity plot of TANGO 286 protein. An alignment of the amino acid sequences of human TANGO 286 ("286"; SEQ ID NO: 405) and BPI protein ("BPI"; SEQ ID NO: 408) protein is shown in Figures 28F and 28G. An alignment of the amino acid sequences

of human TANGO 286 ("286"; SEQ ID NO: 405) and RENP protein ("RENP"; SEQ ID NO: 409) is shown in Figures 28H and 28I.

Figure 29 comprises Figures 29A to 29H. The nucleotide sequence (SEQ ID NO: 415) of a cDNA encoding the human TANGO 294 protein described herein is listed in Figures 29A to 29C. The ORF (residues 126 to 1394; SEQ ID NO: 416) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 417) of human TANGO 294 is listed. An alignment of the amino acid sequences of human TANGO 294 protein ("294"; SEQ ID NO: 417) and a known human lipase protein ("HLP"; SEQ ID NO: 445; GenBank Accession No. NP_004181) is shown in Figures 29D and 29E. Figure 29F is a hydrophobicity plot of TANGO 294 protein. An alignment of the amino acid sequences of human TANGO 294 protein ("294"; SEQ ID NO: 417) and a known human lysosomal acid lipase protein ("LAL"; SEQ ID NO: 411) is shown in Figures 29G and 29H.

Figure 30 comprises Figures 30A to 30G. The nucleotide sequence (SEQ ID NO: 423) of a cDNA encoding the human INTERCEPT 296 protein described herein is listed in Figures 30A to 30C. The ORF (residues 70 to 1098; SEQ ID NO: 424) of the cDNA is indicated by nucleotide triplets, above which the amino acid sequence (SEQ ID NO: 425) of human INTERCEPT 296 protein is listed. Figure 30D is a hydrophobicity plot of INTERCEPT 296 protein. An alignment of the amino acid sequences of human INTERCEPT 296 protein ("296"; SEQ ID NO: 425) and C. elegans C06E1.3 related protein ("CRP"; SEQ ID NO: 410) is shown in Figures 30E through 30G.

DETAILED DESCRIPTION OF THE INVENTION

The present invention is based, at least in part, on the discovery of a variety of cDNA molecules which encode proteins which are herein designated TANGO 202, TANGO 210, INTERCEPT 217, TANGO 229, TANGO 234, TANGO 265, TANGO 276, TANGO 286, INTERCEPT 289, TANGO 292, TANGO 294, INTERCEPT 296, INTERCEPT 297, INTERCEPT 309, TANGO 331, TANGO 332, TANGO 366,

INTERCEPT 394, INTERCEPT 400, TANGO 416, MANGO 419, INTERCEPT 429, and TANGO 457. These proteins exhibit a variety of physiological activities, and are included in a single application for the sake of convenience. It is understood that the allowability or non-allowability of claims directed to one of these proteins has no bearing on the allowability of claims directed to the others. The characteristics of each of these proteins and the cDNAs encoding them are described separately in the ensuing sections. In addition to the full length mature and immature proteins described in the following sections, the invention includes fragments, derivatives, and variants of these proteins, as described herein. These proteins, fragments, derivatives, and variants are collectively referred to herein as polypeptides of the invention or proteins of the invention.

TANGO 416

Expression of cDNA encoding a TANGO 416 protein was up-regulated in porcine endothelial cells that were activated using one or more of bacterial lipopolysaccharide, tumor necrosis factor alpha, and human serum. Up-regulation was detected by extracting total RNA from activated cells and subjecting the RNA to reverse transcriptase polymerase chain reaction for differential display. cDNA clones encoding at least a portion of human TANGO 416 protein and corresponding to the porcine TANGO 416 cDNA were isolated from human fetal spleen and osteoblast cDNA libraries (including a clone designated jthsa97d5 obtained from a fetal spleen library, a clone designated jthoc122e2 obtained from an osteoblast library, and a clone designated jthsa121f10 obtained from a fetal spleen library).

Human TANGO 416 protein is a transmembrane protein which can occur in at least two alternative forms, which differ in the presence or absence of a single amino acid residue (i.e. the glutamine residue at amino acid residue 830 of SEQ ID NO: 3 and corresponding nucleotide residues 2863-2865 in SEQ ID NO: 1). In this application, reference to amino acid and nucleotide residues is made to those residues in the longer form of TANGO 416 (i.e. the form having the amino acid sequence SEQ ID NO: 3 and

the corresponding cDNA and ORF sequences SEQ ID NOs: 1 and 2, respectively).

The longer form of TANGO 416 has a glutamine residue at amino acid residue 830 that is not present in the shorter form of TANGO 416.

It is understood that both forms of TANGO 416 can exhibit the same biological
5 properties, and that references to amino acid residues numbered 831 or higher in SEQ
ID NO: 3 correspond to amino acid residues having the next lower number in SEQ ID
NO: 33 (i.e. amino acid residue 901 in the longer form of TANGO 416 {SEQ ID NO:
3} corresponds to amino acid residue 900 in the shorter form of TANGO 416 {SEQ ID
NO: 33}). Similarly, references to nucleotide residues numbered 2866 or higher in
10 SEQ ID NO: 1 correspond to nucleotide residues having a number that is lower by 3 in
SEQ ID NO: 31 (i.e. nucleotide residue 2903 in the longer form of TANGO 416 {SEQ
ID NO: 1} corresponds to nucleotide residue 2900 in the shorter form of TANGO 416
{SEQ ID NO: 31}).

The full length of a cDNA which was isolated from a human fetal spleen cDNA
15 library and which encodes human TANGO 416 protein (Figure 1; SEQ ID NO: 1; i.e.
the longer form of TANGO 416) is 5121 nucleotide residues. The open reading frame
(ORF) of this cDNA, nucleotide residues 376 to 3780 of SEQ ID NO: 1 (i.e., SEQ ID
NO: 2), encodes a 1135-amino acid residue protein (Figure 1; SEQ ID NO: 3),
corresponding to a 1108-residue transmembrane mature protein.

20 The invention thus includes purified human TANGO 416 protein, both in the
form of the immature 1135 amino acid residue protein (SEQ ID NO: 3, including the
shorter 1134-residue protein {SEQ ID NO: 33}) and in the form of the mature 1108
amino acid residue protein (SEQ ID NO: 5, including the shorter 1107-residue protein
{SEQ ID NO: 35}). Mature human TANGO 416 proteins can be synthesized without
25 the signal sequence polypeptide at the amino terminus thereof, or they can be
synthesized by generating immature TANGO 416 protein and cleaving the signal
sequence therefrom.

The invention includes nucleic acid molecules which encode a polypeptide of
the invention. Such nucleic acids include, for example, a DNA molecule having the

nucleotide sequence listed in SEQ ID NOs: 1, 2, 31, and 32, such as the portion which encodes a mature TANGO 416 protein, an immature TANGO 416 protein, or a domain of a TANGO 416 protein. These nucleic acids are among the nucleic acids of the invention.

5 TANGO 416 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional features. As used in this disclosure, the term "family" means two or more proteins or nucleic acid molecules having a common or similar domain structure and having sufficient amino acid or nucleotide sequence identity as defined herein. Family members can be from
10 either the same or different species (e.g., human and mouse). For example, a family can comprise two or more proteins of human origin, or can comprise one or more proteins of human origin and one or more of non-human origin.

A common domain present in TANGO 416 proteins is a signal sequence. As used herein, a signal sequence includes a peptide of at least about 10 amino acid
15 residues in length which occurs at the amino terminus of membrane-bound and secreted proteins and which contains at least about 45% hydrophobic amino acid residues such as alanine, leucine, isoleucine, phenylalanine, proline, tyrosine, tryptophan, or valine. In one embodiment, a signal sequence contains at least about 10 to 35 amino acid residues, and has at least about 35-60%, more preferably 40-50%, and
20 more preferably at least about 45% hydrophobic residues. A signal sequence serves to direct a protein containing such a sequence to a lipid bi-layer. Thus, in one embodiment, a TANGO 416 protein contains a signal sequence corresponding to amino acid residues 1 to 27 of SEQ ID NO: 3 and 33 (i.e. SEQ ID NO: 4). It is recognized that the carboxyl terminal boundary of the signal sequence can be located
25 one or two residues from the residue identified above (i.e., following residues 25, 26, 27, 28, or 29 of SEQ ID NOs: 3 and 33). The signal sequence is cleaved during processing of the mature protein.

TANGO 416 proteins include a transmembrane domain and two extra-membrane domains flanking the cell membrane. The transmembrane domain

corresponds to about amino acid residues 701 to 721 of SEQ ID NOs: 3 and 33 (i.e., the transmembrane domain having the sequence SEQ ID NO: 7). One of the extra-membrane domains corresponds to about amino acid residues 28 to 700 of SEQ ID NOs: 3 and 33 (i.e. the domain having the sequence SEQ ID NO: 6). The other extra-
5 membrane domain corresponds to about amino acid residues 722 to 1135 of SEQ ID NO: 3 (i.e. residues 722 to 1134 of SEQ ID NO: 33, this domain having the sequence SEQ ID NO: 8 in the longer form of TANGO 416 and SEQ ID NO: 38 in the shorter form). In one embodiment, the extra-membrane domain corresponding to SEQ ID NO: 6 is an extra-cellular domain and the other extra-membrane domain is an intracellular
10 domain. In an alternative embodiment, the extra-membrane domain corresponding to SEQ ID NO: 6 is an intracellular domain and the other extra-membrane domain is an extra-cellular domain.

As used herein, an "extracellular domain" refers to a portion of a protein which is localized to the non-cytoplasmic side of a lipid bi-layer of a cell when a nucleic acid
15 encoding the protein is expressed in the cell. A "transmembrane domain" refers to an amino acid sequence which is at least about 20 to 25 amino acid residues in length and which contains at least about 65-70% hydrophobic amino acid residues such as alanine, leucine, phenylalanine, protein, tyrosine, tryptophan, or valine. As used herein, a "cytoplasmic domain" refers to a portion of a protein which is localized to the
20 cytoplasmic side of a lipid bi-layer of a cell when a nucleic acid encoding the protein is expressed in the cell.

TANGO 416 proteins typically comprise a variety of potential post-translational modification sites and protein domains (often positioned within an extracellular domain), such as those described herein in Table I, as predicted by
25 computerized sequence analysis of TANGO 416 proteins using amino acid sequence comparison software (comparing the amino acid sequence of TANGO 416 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}).

Table I

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 3	Amino Acid Sequence
N-glycosylation site	103 to 106	NCSI

As used herein, the term "post-translational modification site or domain" refers to a protein region that includes about 3 to 10 amino acid residues, more preferably about 3 to 6 amino acid residues wherein the domain has an amino acid sequence which comprises a consensus sequence which is recognized and modified by a protein-modifying enzyme. The term also includes protein domains having greater lengths, as indicated herein. Examples of protein-modifying enzymes include amino acid

glycosylases, cAMP- and cGMP-dependent protein kinases, protein kinase C, casein kinase II, tyrosine kinase, myristoylases, and prenyl transferases. In various embodiments, the protein of the invention has at least 1, 2, 4, 6, 10, 15, 20, 30, 40, or 50 or more of the post-translational modification sites described herein in Table I. In one embodiment, the protein of the invention has all 63 of the sites described in Table I

Examples of additional domains present in human TANGO 416 protein include cadherin extracellular repeated domains. In one embodiment, the protein of the invention has at least one domain or signature sequence that is at least 55%, preferably at least about 65%, 75%, 85%, or 95% identical to one of the cadherin extracellular domains or signature sequences described herein in Table I. Preferably, the protein of the invention has 2, 3, 4, or all 5, cadherin extracellular repeated domains.

Cadherin extracellular repeated domains have a conserved consensus sequence that occurs in numerous cadherins. The conserved extracellular cadherin repeated domain sequence, which is frequently repeated in cadherins is

{L or I or V}-X-{L or I or V}-X_(1 or 2)-D-X-N-D-{N or H}-X-P, (SEQ ID NO: 450)

where X is any amino acid residue, and wherein the subscript '1 or 2' indicates that either one or two X residues can be present at that position. Folding of the extracellular repeated domain of cadherins is believed to roughly correspond to occurrence of extracellular cadherin repeated domains.

Cadherins are a family of cell-surface proteins which are involved in cell-to-cell binding, including specific cell adhesion processes which occur during development and adherens junction formation related to tissue organization in developing and adult organisms. Cadherins are also involved in intracellular signaling. Repeated cadherin extracellular domains occur in a variety of cadherins, including, for example, epithelial cadherin (sometimes designated E-cadherin, uvomorulin, L-CAM, or CDH1), neural cadherin (sometimes designated N-cadherin or CDH2), placental cadherin (sometimes designated P-cadherin or CDH3), retinal cadherin (sometimes designated R-cadherin or CDH4), vascular endothelial cadherin (sometimes designated VE-cadherin or CDH5), kidney cadherin (sometimes designated K-cadherin or CDH6), cadherin-8 (sometimes

designated CDH8), osteoblast cadherin (sometimes designated OB-cadherin or CDH11), brain cadherin (sometimes designated BR-cadherin or CDH12), truncated cadherin (sometimes designated T-cadherin or CDH13), muscle cadherin (sometimes designated M-cadherin or CDH14), liver-intestine cadherin (sometimes designated LI-cadherin), and EP-cadherin. Occurrence of repeated cadherin extracellular domains in TANGO 416 is an indication that TANGO 416 is a member of the cadherin family of proteins, and is thus involved in specific cell adhesion processes and regulation of intracellular signaling events in tissues in which it occurs.

The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that human TANGO 416 protein includes a 27 amino acid residue signal peptide (amino acid residues 1 to 27 of SEQ ID NOs: 3 and 33 {SEQ ID NO: 4}) preceding the mature TANGO 416 protein (about amino acid residues 28 to 1135 of SEQ ID NO: 3 {SEQ ID NO: 5} and about amino acid residues 28 to 1134 of SEQ ID NO: 33 {SEQ ID NO: 35}). Human TANGO 416 protein includes an extracellular domain (about amino acid residues 28 to 700 of SEQ ID NOs: 3 and 33 {SEQ ID NO: 6}), a transmembrane domain (about amino acid residues 701 to 721 of SEQ ID NOs: 3 and 33 {SEQ ID NO: 7}), and an intracellular domain (about amino acid residues 722 to 1135 of SEQ ID NO: 3 {SEQ ID NO: 8} and about amino acid residues 722 to 1134 of SEQ ID NO: 33 {SEQ ID NO: 38}).

Figure 3 depicts a hydrophobicity plot of human TANGO 416 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to 27 of SEQ ID NOs: 3 and 33 is the signal sequence of human TANGO 416 (SEQ ID NO: 4). As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human TANGO 416 protein from about amino acid residue 450 to about amino acid residue 470 appears to be located at

or near the surface of the protein, while the region from about amino acid residue 335 to about amino acid residue 345 appears not to be located at or near the surface.

The predicted molecular weight of human TANGO 416 protein without modification and prior to cleavage of the signal sequence is about 126.0 kilodaltons.

- 5 The predicted molecular weight of the mature human TANGO 416 protein without modification and after cleavage of the signal sequence is about 122.8 kilodaltons.

TANGO 416 DNA maps to chromosome 4, between chromosomal markers D4S422 and D4S1576, as assessed by comparing TANGO 416 sequence with an ESTs in a mapping database. Other genes which map to this chromosomal segment include
10 those encoding endothelin-1 receptor precursor, surfactant protein A, transforming growth factor beta signaling protein-1 (Bsp-1), and a gene highly similar to Mus musculus hemoglobin zeta chain. Thus, disorders previously attributed to these loci by others can also be attributable to the chromosomal portion encoding TANGO 416.

cDNA encoding TANGO 416 protein occurs in cDNA libraries generated from
15 human fetal spleen tissue and from human osteoblasts. High homology of TANGO 416 cDNA was observed with expressed sequence tags (ESTs) obtained from EST libraries generated from human fetal heart, human fetal lung, human testis, human pancreas, human prostate, and human B cell tissues, indicating that TANGO 416 protein can be expressed in these tissues as well.

20 Residues 1651-4000 of SEQ ID NO: 1 (the nucleotide sequence of TANGO 416 cDNA) were aligned (using the ALIGN software with gap length penalty of 12, and a gap penalty of 4) with the nucleotide sequence of the human testis cDNA clone DKFZp434B0923 listed in GenBank accession number AL137471. This alignment, shown in Figure 4, was generated using the ALIGN software (using the BLOSUM62
25 scoring matrix, a gap opening penalty of 12, a gap extension penalty of 4, and a frameshift gap penalty of 5), and indicated 98.6% identity between the two sequences in the 2350-residue overlapping portion. The nucleotide sequence (SEQ ID NO: 2) of the ORF encoding TANGO 416 was aligned using the ALIGN software (with gap length penalty of 12, and a gap penalty of 4)) with the nucleotide sequence of the ORF

of a murine protocadherin (GenBank™ accession number Y08715; Telo et al., 1998, J. Biol. Chem. 273:17565-17572), as shown in Figure 5. This alignment was generated using the ALIGN software (using the BLOSUM62 scoring matrix, a gap opening penalty of 12, a gap extension penalty of 4, and a frameshift gap penalty of 5), and indicated 55.4% identity between the two sequences in the overlapping portion. Alignment of the amino acid sequence of TANGO 416 with the amino acid sequence of the murine protocadherin, as shown in Figure 6, indicated 32.8% sequence identity and 42.2 % sequence similarity. This alignment was generated using the ALIGN software (using the BLOSUM62 scoring matrix, a gap opening penalty of 12, a gap extension penalty of 4).

Uses of TANGO 416 Nucleic acids,
Polypeptides, and Modulators Thereof

TANGO 416 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not expressed. Based on the observations that cDNA corresponding to TANGO 416 occurs in human fetal spleen and human osteoblast cDNA libraries, and that ESTs corresponding to portions of TANGO 416 can be detected in ESTs prepared from each of human fetal heart, human fetal lung, human testis, human pancreas, human prostate, and human B cell tissues, TANGO 416 protein can be involved in one or more biological processes which occur in these tissues. In particular, TANGO 416 can be involved in modulating growth, proliferation, survival, differentiation, adhesion, and activity of cells of these tissues. Furthermore, because TANGO 416 likely belongs to the cadherin family of proteins, it can also be involved in modulating movement of cells (e.g., T cells and other cells of the immune system) through tissues which express receptors for TANGO 416 (e.g. cells which express one or more cadherin receptors, e.g., cells which express integrin $\alpha E\beta 7$).

Integrin $\alpha E\beta 7$ (sometimes designated $\alpha E/HML-1$, αE /human mucosal lymphocyte-1 and CD103, and described in international patent application

publication number WO95/22610, published on August 24, 1995) is an integrin protein which is expressed by more than 90% of intestinal epithelial lymphocytes, on 40-50% of intestinal lamina propria T lymphocytes, and on about 2% of peripheral blood leukocyte. Integrin $\alpha E\beta 7$ is also expressed by T lymphocytes at other mucosal epithelia and on about 40% of T cells obtained by bronchioalveolar lavage. Integrin $\alpha E\beta 7$ is apparently not expressed on B cells. A putative endothelial ligand designated E-cadherin binds with integrin $\alpha E\beta 7$. Antibodies which bind specifically with the αE subunit of integrin $\alpha E\beta 7$ have demonstrated efficacy for treatment of inflammatory bowel disease and for reducing pulmonary inflammation and airway hyper-responsiveness in murine models of these disorders. Integrin $\alpha E\beta 7$ is believed to have a role in binding of lymphocytes with endothelial cells and with regulation of tissue levels of T_H1 and T_H2 cytokines (e.g. IL-5, IL-13) and eotaxin. The ability of TANGO 416 to bind with integrin $\alpha E\beta 7$ indicates that TANGO 416 protein and other TANGO 416-related molecules can be used to modulate the physiological activities associated with integrin $\alpha E\beta 7$ function and to treat disorders to which such physiological activities contribute.

In one embodiment of the invention, TANGO 416-related molecules are used to modulate interaction of cells which normally express integrin $\alpha E\beta 7$ (e.g. binding with, movement over, among, or past, or activation of cellular function by) and cells which normally express TANGO 416. TANGO 416-related molecules can also be used to modulate production, release, or both, of cytokines and eotaxin by cells which normally express integrin $\alpha E\beta 7$. TANGO 416 protein can thus be involved in disorders which affect epithelial and lymphocytic tissues. Such disorders include cell proliferation disorders, disorders associated with aberrant epithelial permeability, auto-, hypo-, and hyper-immune disorders, disorders associated with aberrant binding or adhesion of cells with other cells, and inflammatory disorders. TANGO 416-related molecules can be used to prognosticate, prevent, diagnose, or treat one or more such disorders. Examples of these disorders include acute and chronic inflammatory diseases of the bowel, colitis of various etiologies,

gastrointestinal infections, gastritis, gastroesophageal reflux disorder, acute and chronic peritonitis, appendicitis, diarrhea, constipation, gastroenteritis, hemorrhoids, proctitis, chronic and acute bronchitis, asthma, pneumonia, hypersensitivity pneumonitis, allergic disorders, anemia, leukopenia, thrombocytopenia, lymphoproliferative diseases, transplant rejection, graft-versus-host reactions, allergic reactions, hypersplenism, autoimmune disorders, metastasis of tumor tissue, cystic fibrosis, various chronic obstructive pulmonary disorders, pericarditis, hypogonadism, and testosterone deficiency syndrome.

Other disorders which can be treated using TANGO 416 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these include disorders of bone and cartilage tissues (e.g., traumatic and degenerative injuries), disorders of the spleen (e.g., lymphoma and splenomegaly), disorders associated with aberrant processing of blood cells in splenic tissue (e.g., disorders involving aberrant macrophage activity), cardiovascular disorders (e.g., disorders of the cardiac muscle and disorders of blood vessels), disorders involving aberrant association (or non-association) of B and T lymphocytes with each other and with endothelial tissues (e.g., immune disorders and inflammatory disorders), pancreatic disorders (e.g., pancreatitis, pancreatic cysts, pancreatic tumors, diabetes mellitus, and islet cell tumors), and disorders of the prostate (e.g., inflammatory prostatic diseases, prostatic hyperplasia, and prostate tumors).

TANGO 416 can interact as a ligand with integrin $\alpha E\beta 7$, as discussed above. Integrin $\alpha E\beta 7$ (also designated human mucosal lymphocyte 1 antigen or CD103) is expressed on more than 90% of intestinal epithelial lymphocytes (IEL), and about 40-50% of intestinal lamina propria T lymphocytes, but only on about 2% of peripheral blood leukocytes. Integrin $\alpha E\beta 7$ is also expressed on T lymphocytes which are present at other mucosal epithelial (e.g. on about 40% of T cells recovered by bronchioalveolar lavage {BAL}). Integrin $\alpha E\beta 7$ does not appear to be expressed on B lymphocytes. Transforming growth factor beta 1 (TGF- $\beta 1$) induces expression of integrin $\alpha E\beta 7$ on both T lymphocytes and cultured murine mast cells.

Antibodies which bind specifically with integrin $\alpha E\beta 7$ reduce morbidity and pathological effects associated with experimentally induced inflammatory bowel disease (IBD; e.g. using the CD45Rb^{hi} SCID transfer model of IBD), transmural colitis, (e.g. using interleukin-2 {IL-2} knockout mice immunized using 2,4,6-trinitrophenol),
5 and pulmonary inflammation (e.g. using mice sensitized intraperitoneally with and challenged with aerosol ovalbumin). In BAL fluids obtained from mice which were sensitized and challenged with ovalbumin and to which anti-integrin $\alpha E\beta 7$ were administered, decreased numbers of eosinophils and leukocytes were detected, and levels of T_H2 cytokines (e.g. IL-5 and IL-13) and eotaxin were decreased as well.
10 Integrin $\alpha E\beta 7$ knockout (i.e. nullizygous) mice exhibited decreased numbers of intestinal epithelial lymphocytes, decreased susceptibility to pulmonary inflammation, reduced airway hyper-responsiveness, and decreased levels of T_H2 cytokines in BAL fluids. These data indicate that integrin $\alpha E\beta 7$ can function as a receptor for guiding lymphocytes (e.g. T cells, mast cells, and eosinophils) to mucosal epithelia and
15 maintaining them at those locations. These data also indicate that integrin $\alpha E\beta 7$ can modulate T_H1 and T_H2 cytokine levels in tissues which contain integrin $\alpha E\beta 7$ -bearing cells (see international patent application publication number WO95/22610, published on August 24, 1995).

TANGO 416 proteins can bind with integrin $\alpha E\beta 7$ and thereby modulate the
20 integrin's physiological effects. In particular, TANGO 416 proteins can modulate localization of integrin $\alpha E\beta 7$ -bearing lymphocytes at tissues which express TANGO 416 (e.g. at mucosal epithelia such as intestinal and pulmonary epithelia) and release and maintenance of T_H1 and T_H2 cytokine levels in or near such tissues. Modulation of cytokine levels by TANGO 416 can, in turn, modulate proliferation, activity, and
25 migration of cells of the immune system, such as are associated with a variety of inflammatory, auto-immune, hypo-immune, and hyper-immune disorders. TANGO 416 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can thus be used to modulate these processes.

Disorders that involve proliferation, activity, and migration of immune cells in the vicinity of mucosal epithelia include, by way of example, acute and chronic inflammatory diseases of the bowel (e.g. inflammatory bowel disease and Crohn's disease), colitis (of various etiologies), gastrointestinal infections (e.g. formation and
5 perseverance of peptic ulcers), gastritis, gastroesophageal reflux disorder, acute and chronic peritonitis, appendicitis, diarrhea, constipation, gastroenteritis, hemorrhoids, and proctitis. Such disorders also include disorders that involve proliferation, activity, and migration of immune cells in the vicinity of pulmonary mucosal epithelial, such as chronic and acute bronchitis, asthma, pneumonia (e.g. pneumococcal, staphylococcal,
10 streptococcal, klebsiellal, hemophilal, viral, fungal, etc.), hyper-sensitivity pneumonitis, and allergic disorders (e.g. hay fever and the like). TANGO 416 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can thus be used to prognosticate, diagnose, and treat one or more of these disorders.

15 Expression of TANGO 416 in osteoblasts is an indication that TANGO 416 can have a role in modulating bone formation, marrow cell differentiation and proliferation, and proliferation, differentiation, function, or some combination of these, of bone and cartilage cells. Examples of disorders which can be prognosticated, diagnosed, and treated using TANGO 416 proteins, nucleic acids encoding them, and agents that
20 modulate activity or expression of either of these include disorders of bone and cartilage tissues including bone or cartilage injuries, such as those attributable to trauma (e.g., bone breakage and cartilage tearing), or to degeneration (e.g., osteoporosis and age-related degradation of cartilage). The compositions can also be used to treat disorders associated with degeneration of joints, such as arthritis
25 (including rheumatoid arthritis), osteoarthritis, and bone wearing.

Occurrence of TANGO 416 cDNA in a fetal spleen library is an indication that TANGO 416 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to modulate proliferation, differentiation, function, or some combination of these, of spleen cells (e.g., cells of the splenic

connective tissue, splenic smooth muscle cells, and endothelial cells of splenic blood vessels). These compositions can thus be used to treat disorders of the spleen, (including both the fetal spleen and the adult spleen). Examples of splenic diseases and disorders include splenic lymphoma and splenomegaly. Occurrence of TANGO 416 in
5 splenic tissue further indicates that TANGO 416 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to modulate proliferation, differentiation, function, or some combination of these, of blood cells that are processed in splenic tissue. These cells include cells which are regenerated or phagocytized within the spleen, including, for example, erythrocytes, B
10 and T lymphocytes, and macrophages. Examples of these disorders include phagocytotic disorders, such as disorders in which engulfment of bacteria and viruses in the bloodstream by macrophages in the spleen is inhibited.

Occurrence in a fetal heart library of an EST which exhibits homology with cDNA encoding TANGO 416 indicates that TANGO 416 proteins, nucleic acids
15 encoding them, and agents that modulate activity or expression of either of these can be used to treat cardiovascular disorders, including disorders of the heart and disorders of the blood vessels. Examples of cardiac disorders which can be treated in this manner include ischemic heart diseases (e.g., angina pectoris, myocardial infarction and its aftermath, coronary artery disease, cardiac arrest, and chronic ischemic heart disease),
20 hypertensive heart disease, pulmonary heart disease, valvular heart disease (e.g., rheumatic fever and rheumatic heart disease, endocarditis, mitral valve prolapse, and aortic valve stenosis), congenital heart disease (e.g., valvular and vascular obstructive lesions, atrial or ventricular septal defect, and patent ductus arteriosus), cardiac arrhythmia, cardiac insufficiency, endocarditis, pericardial disease, muscular
25 dystrophy, and myocardial disease (e.g., myocarditis, congestive cardiomyopathy, restrictive cardiomyopathy, and hypertrophic cardiomyopathy). Examples of vascular disorders which can be treated in this manner include arteriosclerosis, atherosclerosis, hypertension, aberrant or non-desired angiogenesis, stenosis and restenosis, and smooth muscle proliferation in response to traumatic injury.

Involvement of TANGO 416 protein in binding of cells is an indication that TANGO 416 can be involved in disorders associated with aberrant binding or adhesion of cells with other cells, with extracellular matrix, or with foreign materials. Disorders involving aberrant binding or adhesion of cells with other cells include both disorders
5 in which cells normally bind with one another (e.g., metastasis of normally solid tumor tissue cells away from the tumor site of origin or immune hypersensitivity) and disorders in which the cells do not normally bind with one another, but do bind with one another in individuals afflicted with the disorder (e.g., metastasis of tumor cells into a tissue in which the cells do not normally occur, autoimmune disorders,
10 infections, wherein cells with which T cells bind are not normally present in the animal, or disorders associated with abnormal blood coagulation). Disorders involving aberrant binding or adhesion of cells with tissue on which TANGO 416 is normally expressed, include those in which the cells normally do, but aberrantly do not, bind with TANGO 416-expressing tissue as well as those (e.g., metastasis of cancers cells
15 into mucosal epithelium) in which the cells normally do not bind with TANGO 416-expressing tissue, but aberrantly do. TANGO 416 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

Like many transmembrane signaling proteins, TANGO 416 protein comprises
20 extracellular domains capable of interacting with environmental cues (e.g., the presence or absence of particular cells, proteins, or small molecules) and a cytoplasmic domain having a substantial size. Numerous cadherins interact with catenins, tyrosine kinases, and other proteins which can influence the structure of the intracellular matrix. TANGO 416 can also interact with such proteins, and the existence of numerous post-
25 translationally modifiable sites (see Table I) on TANGO 416 is an indication that TANGO 416 can be involved in transducing signals across the cell membrane. Binding of a ligand of TANGO 416 protein (e.g. integrin $\alpha E\beta 7$ on the surface of a different cell such as a leukocyte) with a portion of the protein located on one side of the membrane can affect one or more characteristics (e.g., conformation,

phosphorylation state, or level or specificity of enzymatic activity) of a portion of the TANGO 416 protein located on the other side. Thus, for example, a compound in the extracellular environment of a cell which expresses TANGO 416 can bind with the extracellular domain of the protein, thereby effecting a change in a characteristic of the intracellular portion of the protein, leading to alteration of the physiology of the cell (e.g., effected by an activity exerted by the intracellular portion of the protein on another component of the cell). The compound in the extracellular environment can, for example, be a compound dissolved or suspended in a liquid, a compound attached to another cell of the same animal, or a compound attached to a foreign cell or virus particle.

TANGO 416 protein can associate with other signal transduction proteins in the cell membrane, thereby modulating the intracellular activity of those other proteins. TANGO 416 can also bind with a membrane-bound protein (e.g. integrin $\alpha E\beta 7$) of another cell, thereby modulating physiological activities associated with signal transduction mediated by that membrane-bound protein. By way of example, signal transduction events associated with integrin $\alpha E\beta 7$ include modulation of T_H1 and T_H2 cytokine (and eotaxin) production and release by leukocytes and movement and adherence of leukocytes. TANGO 416 protein and fragments and variants thereof can modulate such activities. TANGO 416 proteins can thus have a role in disorders which involve aberrant transmembrane signal transduction. Examples of signal transduction-related disorders include cystic fibrosis, various chronic obstructive pulmonary disorders, lymphocyte localization and activation disorders (e.g. transmural colitis, airway hyper-responsiveness, and various allergic disorders), and inflammatory disorders such as inflammatory bowel disease. TANGO 416 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

Occurrence of ESTs which exhibit homology with TANGO 416 nucleic acids in EST libraries generated from tissues which comprise endothelial tissues (e.g. fetal heart tissue and testicular tissue) indicates that TANGO 416-related molecules can be

used to prognosticate, diagnose, and treat one or more other disorders which afflict endothelial tissues and organs which contain them. By way of example, the heart is surrounded by an endothelial pericardium which can become inflamed, leading to pericarditis and other complications. Similarly, the endothelial lining of blood vessels is known to bind lymphocytes (e.g. during 'rolling' movement of lymphocytes through the vessel and during extravasation of lymphocytes). Disorders which can affect testicular endothelium include hypogonadism and testosterone deficiency syndrome. Interaction of one or more TANGO 416-related molecules with cells that modulate interaction of TANGO 416 with integrin $\alpha E\beta 7$ cells can inhibit, prevent, or alleviate such disorders. Furthermore, interaction of TANGO 416-related molecules with sample material (e.g. blood or tissue) obtained by a patient can be used to diagnose such disorders.

Homology of an EST obtained from a human B cell EST library with a TANGO 416 nucleic acid is an indication that TANGO 416 can modulate disorders involving inappropriate interaction of B and T cells. Such disorders include hypo-, hyper-, and auto-immune disorders and also include inflammatory disorders. By modulating interactions of B and T lymphocytes with each other and with endothelial tissues (and other tissues which can express integrin $\alpha E\beta 7$, TANGO 416 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can also be used to treat immune disorders and inflammatory disorders. By way of example, they can be used to treat autoimmune disorders (e.g., arthritis, graft rejection such as allograft rejection), T cell disorders (e.g., AIDS)), bacterial infection, psoriasis, bacteremia, septicemia, cerebral malaria, inflammatory bowel disease, arthritis (e.g., rheumatoid arthritis, osteoarthritis), and allergic inflammatory disorders (e.g., asthma or psoriasis).

Homology of an EST of a library made using cDNA obtained from pancreatic tissue with TANGO 416 cDNA sequence indicates that TANGO 416 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to treat pancreatic disorders. Examples of pancreatic disorders which can

be treated in this manner include pancreatitis (e.g., acute hemorrhagic pancreatitis and chronic pancreatitis), pancreatic cysts (e.g., congenital cysts, pseudocysts, and benign or malignant neoplastic cysts), pancreatic tumors (e.g., pancreatic carcinoma and adenoma), diabetes mellitus (e.g., insulin- and non-insulin-dependent types, impaired
5 glucose tolerance, and gestational diabetes), and islet cell tumors (e.g., insulinomas, adenomas, Zollinger-Ellison syndrome, glucagonomas, and somatostatinoma).

cDNA encoding TANGO 416 also exhibits homology with an EST of a library made using cDNA obtained from prostate tissue. Thus, TANGO 416 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these
10 can be used to treat prostate disorders. Examples of prostate disorders which can be treated in this manner include inflammatory prostatic diseases (e.g., acute and chronic prostatitis and granulomatous prostatitis), prostatic hyperplasia (e.g., benign prostatic hypertrophy or hyperplasia), and prostate neoplasms and tumors (e.g., carcinomas).

Homology of TANGO 416 protein with murine vascular endothelial cadherin-2
15 (mVE-cad-2; Telo et al., 1998, J. Biol. Chem. 273:17565-17572; GenBank™ accession number Y08715; sometimes designated protocadherin; see Figures 5 and 6) is an indication that TANGO 416 is a human orthologue of that mVE-cad-2, and exhibits one or more of the same activities. That is, TANGO 416 can be involved in adherens junction formation and maintenance, and can thereby modulate endothelial
20 permeability to plasma proteins and circulating cells.

TANGO 457

The TANGO 457 proteins and nucleic acid molecules comprise families of molecules having certain conserved structural and functional features.

25 For example, the TANGO 457 proteins of the invention can have signal sequences. In certain embodiments, a TANGO 457 polypeptide can include the amino acid sequence SEQ ID NO: 55 at its amino terminus, and the signal sequence is located at amino acids 1 to 21, 1 to 22, 1 to 23, 1 to 24, 1 to 25, 1 to 26, or 1 to 27 of SEQ ID NO: 53. In such embodiments of the invention, the domains and the mature protein

resulting from cleavage of such signal peptides are also included herein. For example, the cleavage of a signal sequence consisting of amino acids 1 to 24 of SEQ ID NO: 53 (SEQ ID NO: 55) results in a cytoplasmic domain consisting of amino acids 25 to 264, a transmembrane domain consisting of amino acids 265 to 282, an extracellular domain
5 consisting of amino acids 283 to 365, of SEQ ID NO: 53 (SEQ ID NO: 56, 59, and 60, respectively) and the mature TANGO 457 protein corresponding to amino acids 25 to 365 of SEQ ID NO: 53 (SEQ ID NO: 54). The signal sequence is normally cleaved during processing of the mature protein.

A TANGO 457 family member can include one or more of the following
10 domains: (1) an extracellular domain; (2) a transmembrane domain; and (3) a cytoplasmic domain. For example, in one embodiment, a TANGO 457 protein contains a cytoplasmic domain at about amino acid residues 1 to 264 of SEQ ID NO: 53 (SEQ ID NO: 56), a transmembrane domain at about amino acid residues 265 to 282 of SEQ ID NO: 53 (SEQ ID NO: 59), and an extracellular domain at about amino
15 acid residues 283 to 365 of SEQ ID NO: 53 (SEQ ID NO: 60). In another embodiment, a human TANGO 457 protein contains an cytoplasmic domain at amino acid residues 283 to 365 of SEQ ID NO: 53 (SEQ ID NO: 60), a transmembrane domain at amino acid residues 265 to 282 of SEQ ID NO: 53 (SEQ ID NO: 59), and an extracellular domain at amino acid residues 1 to 264 of SEQ ID NO: 53 (SEQ ID
20 NO: 56).

A TANGO 457 family member can include one or more TANGO 457 Ig domains. A TANGO 457 Ig domain as described herein is about 68 to 84 amino acid residues in length and has the following consensus sequence, beginning about 1 to 15 amino acid residues, more preferably about 3 to 10 amino acid residues, and most
25 preferably about 5 amino acid residues from the domain C-terminus: [FYL]-X-C-X-[VA], wherein [FYL] is a phenylalanine, tyrosine or leucine residue (preferably tyrosine), where "X" is any amino acid, C is a cysteine residue, and [VA] is an alanine residue or a valine residue. In one embodiment, a TANGO 457 family member includes one or more Ig domains having an amino acid sequence that is at least about

55%, preferably at least about 65%, more preferably at least about 75%, yet more preferably at least about 85%, and most preferably at least about 95% identical to amino acids 41 to 124 of SEQ ID NO: 53 (SEQ ID NO: 57). In another embodiment, a TANGO 457 family member includes one or more Ig domains having an amino acid sequence that is at least about 55%, preferably at least about 65%, more preferably at least about 75%, yet more preferably at least about 85%, and most preferably at least about 95% identical to amino acids 163 to 230 of SEQ ID NO: 53 (SEQ ID NO: 58).

In another embodiment, a TANGO 457 family member includes one or more TANGO 457 Ig domains having an amino acid sequence that is at least about 55%, preferably at least about 65%, more preferably at least about 75%, yet more preferably at least about 85%, and most preferably at least about 95% identical to amino acids 41 to 124 and/or 163 to 230 of SEQ ID NO: 53 (SEQ ID NO: 57 and 58), and has a conserved cysteine residue about 1 to 15, preferably 1 to 10, more preferably 1 to 8 residues downstream from the N-terminus of the Ig domain. Thus, in this embodiment, amino acids 48 and 163 of SEQ ID NO: 53 are cysteine residues.

In another embodiment, a TANGO 457 family member includes one or more TANGO 457 Ig domains having an amino acid sequence that is at least 55%, preferably at least about 65%, more preferably at least about 75%, yet more preferably at least about 85%, and most preferably at least about 95% identical to amino acids 41 to 124 and/or 163 to 230 of SEQ ID NO: 53 (SEQ ID NO: 57 and 58), and has a conserved cysteine residue about 1 to 8 residues downstream from the N-terminus of the TANGO 457 Ig domain, has a conserved cysteine within the consensus sequence that forms a disulfide with said first conserved cysteine, and has at least one TANGO 457 biological activity as described herein.

A cDNA encoding human TANGO 457 was identified by analyzing the sequences of clones present in a human uterine smooth muscle library for sequences that encode wholly secreted or transmembrane proteins. This analysis led to the identification of a clone, jthUa027h12, encoding human TANGO 457. The human TANGO 457 cDNA of this clone is 2330 nucleotides long (Figure 7; SEQ ID NO: 51).

The open reading frame of TANGO 457 comprises nucleotides 149 to 1243 of SEQ ID NO: 51 (SEQ ID NO: 52), and encodes a transmembrane protein comprising the 365 amino acid sequence depicted in Figure 7 (SEQ ID NO: 53).

5 The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that human TANGO 457 includes a 24 amino acid signal peptide (amino acids 1 to about amino acid 24 of SEQ ID NO: 53)(SEQ ID NO: 55) preceding the mature TANGO 457 protein (corresponding to about amino acid 25 to amino acid 365 of SEQ ID NO: 53; SEQ ID NO: 54). Human TANGO 213 is predicted to have a molecular weight of approximately 40.6 kilodaltons prior to
10 cleavage of its signal peptide and a molecular weight of approximately 38.0 kilodaltons subsequent to cleavage of its signal peptide.

Secretion assays indicate that the polypeptide encoded by human TANGO 457 is not secreted and thus, likely a transmembrane protein. The secretion assays were performed essentially as follows: 8×10^5 293T cells were plated per well in a 6-well
15 plate and the cells were incubated in growth medium (DMEM, 10% fetal bovine serum, penicillin/ streptomycin) at 37°C, 5% CO₂ overnight. 293T cells were transfected with 2 micrograms of full-length TANGO 457 inserted in the pMET7 vector/well and 10 micrograms LipofectAMINE (GIBCO/BRL Cat. # 18324-012) /well according to the protocol for GIBCO/BRL LipofectAMINE. The transfectant
20 was removed 5 hours later and fresh growth medium was added to allow the cells to recover overnight. The medium was removed and each well was gently washed twice with DMEM without methionine and cysteine (ICN Cat. # 16-424-54). Next, 1 ml DMEM without methionine and cysteine with 50 microcuries of Trans-³⁵S (ICN Cat. # 51006) was added to each well and the cells were incubated at 37°C, 5% CO₂ for the
25 appropriate time period. A 150 microliters aliquot of conditioned medium was obtained and 150 microliters of 2× SDS sample buffer was added to the aliquot. The sample was heat-inactivated and loaded on a 4-20% SDS-PAGE gel. The gel was fixed and the presence of secreted protein was detected by autoradiography.

Figure 8 depicts a hydrophobicity plot of the human TANGO 457 amino acid sequence shown in Figure 7. Relatively hydrophobic regions of the protein are shown above the horizontal line, and relatively hydrophilic regions of the protein are below the horizontal line. The cysteine residues (cys) and N-glycosylation site are indicated by short vertical lines just below the hydrophobicity trace.

In one embodiment, a TANGO 457 protein contains a cytoplasmic domain at about amino acid residues 1 to 264 of SEQ ID NO: 53 (SEQ ID NO: 56), a transmembrane domain at about amino acid residues 265 to 282 of SEQ ID NO: 53 (SEQ ID NO: 59), and an extracellular domain at about amino acid residues 283 to 365 of SEQ ID NO: 53 (SEQ ID NO: 60). In another embodiment, a human TANGO 457 protein contains an cytoplasmic domain at amino acid residues 283 to 365 of SEQ ID NO: 53 (SEQ ID NO: 60), a transmembrane domain at amino acid residues 265 to 282 of SEQ ID NO: 53 (SEQ ID NO: 59), and an extracellular domain at amino acid residues 1 to 264 of SEQ ID NO: 53 (SEQ ID NO: 56).

Human TANGO 457 includes an Ig domain at amino acids 41 to 124 and 163 to 230 of SEQ ID NO: 53, (SEQ ID NO: 57 and 8).

Seven N-glycosylation sites are present in TANGO 457. The first has the sequence NVTI (at amino acid residues 43 to 46 of SEQ ID NO: 53), the second has the sequence NITS (at amino acid residues 57 to 60 of SEQ ID NO: 53), the third has the sequence NITW (at amino acid residues 174 to 177 of SEQ ID NO: 53), the fourth has the sequence NVTs (at amino acid residues 208 to 211 of SEQ ID NO: 53), the fifth has the sequence NSSQ (at amino acid residues 216 to 219 of SEQ ID NO: 53), the sixth has the sequence NFTL (at amino acid residues 242 to 245 of SEQ ID NO: 53), and the seventh has the sequence NFSI (at amino acid residues 260 to 263 of SEQ ID NO: 53). TANGO 457 has one glycosaminoglycan attachment site with the sequence SGVG at amino acid residues 331 to 334 of SEQ ID NO: 53. Six protein kinase C phosphorylation sites are present in TANGO 457. The first has the sequence TWR (at amino acid residues 2 to 4 of SEQ ID NO: 53), the second has the sequence SLR (at amino acid residues 106 to 108 of SEQ ID NO: 53), the third has the sequence

TQK (at amino acid residues 181 to 183 of SEQ ID NO: 53), the fourth has the sequence TIK (at amino acid residues 199 to 201 of SEQ ID NO: 53), the fifth has the sequence TEK (at amino acid residues 255 to 257 of SEQ ID NO: 53), and the sixth has the sequence SKK (at amino acid residues 301 to 303 of SEQ ID NO: 53).

- 5 TANGO 457 has three casein kinase II phosphorylation sites. The first has the sequence TEGD (at amino acid residues 22 to 25 of SEQ ID NO: 53), the second has the sequence SSQE (at amino acid residues 217 to 220 of SEQ ID NO: 53), and the third has the sequence SLSE (at amino acid residues 251 to 254 of SEQ ID NO: 53). TANGO 457 has one tyrosine kinase phosphorylation site with the sequence
- 10 KENEDKY at amino acid residues 155 to 161 of SEQ ID NO: 53. Two N-myristoylation sites are present in TANGO 457. The first has the sequence GMKENE (at amino acid residues 153 to 158 of SEQ ID NO: 53) and the second has the sequence GNVGCV (at amino acid residues 334 to 339 of SEQ ID NO: 53). Lastly, TANGO 457 has an immunoglobulin and major histocompatibility complex protein site with the
- 15 sequence YQCVVRH at amino acid residues 226 to 232 of SEQ ID NO: 53.

Figure 9 depicts a local alignment of the nucleic acid of human TANGO 457 shown in SEQ ID NO: 51 and a portion of the nucleotide sequence of human chromosome 11p14.3 PAC clone pDJ239b22, from nucleic acids 121077 to 122478 (SEQ ID NO: 61; AC003969). The alignment shows that there is a 100% nucleotide

20 sequence identity between the TANGO 457 sequence of SEQ ID NO: 51 and human chromosome 11p14.3 PAC clone pDJ239b22, over the specified region. Genes known to map to the p14 region of human chromosome 11 include those encoding fetal brain protein 239 and hepatitis B virus integration site-1 (see

<http://www.ncbi.nlm.nih.gov/htbin-post/Omim/getmap?d3076>).

- 25 Expressed sequence tags (ESTs) which exhibit homology to TANGO 457 (SEQ ID NO: 51) have been isolated from a B-cell leukemia cell line and from fetal liver, fetal spleen, and placenta tissues. The dbEST accession numbers of these ESTs are AI361759, AA004711, AA004711, and AI189960, respectively. TANGO 457 (SEQ ID NO: 51) exhibits about 80% homology to AI361759 over about 445 base pairs,

from nucleotides 1861 to 2306 of TANGO 457. TANGO 457 (SEQ ID NO: 51) exhibits about 77% homology to AA004711 over about 375 base pairs, from nucleotides 1830 to 2205 of TANGO 457. TANGO 457 (SEQ ID NO: 51) exhibits about 81% homology to AI189960 over about 415 base pairs, from nucleotides 1908 to
5 2320.

Uses of TANGO 457 Nucleic acids,
Polypeptides, and Modulators Thereof

TANGO 457 proteins are involved in disorders which affect both tissues in
10 which they are normally expressed and tissues in which they are normally not expressed. Based on the observations that cDNA corresponding to TANGO 457 occurs in a uterine smooth muscle cDNA library, bears homology to human chromosome 11p14.3 PAC clone pDJ239b22, and bears homology to ESTs isolated from B-cell leukemia, liver, spleen, and placenta libraries, it is evident that TANGO
15 457 protein is involved in one or more biological processes which occur in these tissues. In particular, TANGO 457 is involved in modulating proliferation, migration, morphology, differentiation, and/or function of cells of these tissues. Relevant disorders which involve these tissues are discussed separately below.

As TANGO 457 was originally found in a uterine smooth muscle library,
20 TANGO 457 polypeptides, nucleic acids, or modulators thereof, can be used to modulate the proliferation, migration, morphology, differentiation, and/or function of cells that form the uterus, e.g., endometrium endothelial cells and mesometrium smooth muscle cells, and thus to treat uterine disorders such as, e.g., hyperplasia of the endometrium, dysfunctional uterine bleeding (DUB), and uterine cancers (e.g., uterine
25 leiomyomoma, uterine cellular leiomyoma, leiomyosarcoma of the uterus, malignant mixed mullerian tumor of uterus, uterine sarcoma). TANGO 457 polypeptides, nucleic acids, or modulators thereof can also be used to treat other reproductive disorders, including ovulation disorder, blockage of the fallopian tubes (e.g., due to pelvic inflammatory disease or endometriosis), disorders due to infections (e.g., toxic shock

syndrome, chlamydia infection, Herpes infection, human papillomavirus infection), and ovarian disorders (e.g., ovarian endometriosis and ovarian cancers such as ovarian fibroma and ovarian teratoma).

As TANGO 457 bears homology to regions of human chromosome 11p14.3
5 PAC clone pDJ239b22, and since human chromosome 11p14.3 is the location to which such genes as those encoding fetal brain protein 239 and hepatitis B virus integration site-1 are known to map, TANGO 457 nucleic acids, proteins, and modulators thereof can be used to modulate or treat disorders associated with hepatitis B infection (e.g., hepatitis, e.g., hepatitis B, and hepatocellular carcinomas) as well as CNS related
10 disorders. Such CNS related disorders include but are not limited to bacterial and viral meningitis, Alzheimer's Disease, Huntington's disease, cerebral toxoplasmosis, Parkinson's disease, multiple sclerosis, brain cancers (e.g., cancers that have metastasized from other tissues (e.g., metastatic carcinoma of the brain), cancers of the supportive tissue of the brain (e.g., the glia; including cancers such as glioblastoma and
15 astrocytoma), and cancers of other neural tissues (e.g., acoustic neuroma)), hydrocephalus, and encephalitis.

TANGO 457 is also expressed in the fetal liver, TANGO 457 nucleic acids, proteins, and modulators thereof can be used to modulate the proliferation, migration, morphology, differentiation, and/or function of cells that form the liver, e.g.,
20 hepatocytes, and thus to treat hepatic (liver) disorders, such as jaundice, hepatic failure, hereditary hyperbilirubinemias (e.g., Gilbert's syndrome, Crigler-Naijar syndromes and Dubin-Johnson and Rotor's syndromes), hepatic circulatory disorders (e.g., hepatic vein thrombosis and portal vein obstruction and thrombosis), hepatitis (e.g., chronic active hepatitis, acute viral hepatitis, and toxic and drug-induced hepatitis), hepatic
25 adverse drug reactions such as hepatotoxicity, fibrosis, cirrhosis (e.g., alcoholic cirrhosis, biliary cirrhosis, and hemochromatosis), and hepatic neoplasms and tumors (e.g., primary carcinoma, hepatoblastoma, and angiosarcoma).

In addition, TANGO 457 is expressed in the fetal spleen. TANGO 457 nucleic acids, proteins, and modulators thereof can be used to modulate proliferation,

migration, morphology, differentiation, function, or some combination of these, of cells that form the spleen, (e.g., cells of the splenic connective tissue, splenic smooth muscle cells, or endothelial cells of the splenic blood vessels) or of blood cells that are processed (e.g., regenerated, matured, or phagocytized) within the spleen, as described
5 elsewhere in this disclosure.

As both fetal spleen and fetal liver are sites of hematopoiesis, TANGO 457 nucleic acids, proteins, and modulators thereof can also be used to modulate the proliferation, migration, morphology, differentiation, and/or function of hematopoietic cells, e.g., pluripotential stem cells (e.g., lymphoid cells and myeloid cells), and can be
10 used to treat hematological disorders.

Hematological disorders include, but are not limited to, disorders associated with abnormal differentiation or hematopoiesis, morphology, migration, proliferation, or function of blood cells derived, for example, from myeloid multipotential cells in bone marrow, such as megakaryocytes (and ultimately platelets), monocytes,
15 erythrocytes, and granulocytes (e.g., neutrophils, eosinophils, and basophils) and from lymphoid multipotential cells, such as T and B lymphocytes.

Platelet associated disorders include, but are not limited to, thrombocytopenia due to a reduced number of megakaryocytes in the bone marrow, for example, as a result of chemotherapy; invasive disorders, such as leukemia, idiopathic or drug- or
20 toxin-induced aplasia of the marrow, or rare hereditary amegakaryocytic thrombocytopenias; ineffective thrombopoiesis, for example, as a result of megaloblastic anemia, alcohol toxicity, vitamin B12 or folate deficiency, myelodysplastic disorders, or rare hereditary disorders (e.g., Wiskott-Aldrich syndrome and May-hegglin anomaly); a reduction in platelet distribution, for example, as a result
25 of cirrhosis, a splenic invasive disease (e.g., Gaucher's disease), or myelofibrosis with extramedullary myeloid metaplasia; increased platelet destruction, for example, as a result of removal of IgG-coated platelets by the mononuclear phagocytic system (e.g., idiopathic thrombocytopenic purpura (ITP), secondary immune thrombocytopenia (e.g., systemic lupus erythematosus, lymphoma, or chronic lymphocytic leukemia),

drug-related immune thrombocytopenias (e.g., as with quinidine, aspirin, and heparin), post-transfusion purpura, and neonatal thrombocytopenia as a result of maternal platelet autoantibodies or maternal platelet alloantibodies). Also included are thrombocytopenia secondary to intravascular clotting and thrombin induced damage to platelets as a result of, for example, obstetric complications, metastatic tumors, severe gram-negative bacteremia, thrombotic thrombocytopenic purpura, or severe illness. Also included is dilutional thrombocytopenia, for example, due to massive hemorrhage. Platelet associated disorders also include, but are not limited to, essential thrombocytosis and thrombocytosis associated with, for example, splenectomy, acute or chronic inflammatory diseases, hemolytic anemia, carcinoma, Hodgkin's disease, lymphoproliferative disorders, and malignant lymphomas.

Erythrocyte associated disorders include anemias such as, for example, hemolytic anemias due to hereditary cell membrane abnormalities, such as hereditary spherocytosis, hereditary elliptocytosis, and hereditary pyropoikilocytosis; hemolytic anemias due to acquired cell membrane defects, such as paroxysmal nocturnal hemoglobinuria and spur cell anemia; hemolytic anemias caused by antibody reactions, for example to the RBC antigens, or antigens of the ABO system, Lewis system, Ii system, Rh system, Kidd system, Duffy system, and Kell system; methemoglobinemia; a failure of erythropoiesis, for example, as a result of aplastic anemia, pure red cell aplasia, myelodysplastic syndromes, sideroblastic anemias, and congenital dyserythropoietic anemia; secondary anemia in non-hematologic disorders, for example, as a result of chemotherapy, alcoholism, or liver disease; anemia of chronic disease, such as chronic renal failure; and endocrine deficiency diseases.

Other erythrocyte associated disorders include polycythemias such as, for example, polycythemia vera, secondary polycythemia, and relative polycythemia.

Neutrophil associated disorders include neutropenias that result from or accompany a number of conditions, including, but not limited to, chemotherapy; chronic idiopathic neutropenia; Felty's syndrome, acute infectious disease, lymphoma or aleukemic lymphocytic leukemia, myelodysplastic syndrome, and rheumatic

diseases such as systemic lupus erythematosus, rheumatoid arthritis, and polymyositis. Also included is neutrophilia, for example, accompanying chronic myelogenous leukemia.

Other hematological disorders include disorders associated with abnormal
5 monocyte and/or macrophage function, such as impaired phagocytosis, chemotaxis, or secretion of cytokines, growth factors and acute-phase reactants, resulting from certain diseases, e.g., lysosomal storage diseases (e.g., Gaucher's disease); impaired monocyte cytokine production, for example, found in some patients with disseminated non-tuberculous mycobacterial infection who are not infected with HIV; leukocyte adhesion
10 deficiency (LAD), hyperimmunoglobulin E-recurrent infection (HIE) or Job's syndrome, Chédiak-Higashi syndrome (CHS), and chronic granulomatous diseases (CGD), certain autoimmune diseases, such as systemic lupus erythematosus and other autoimmune diseases characterized by tissue deposition of immune complexes, as seen in Sjögren's syndrome, mixed cryoglobulinemia, dermatitis herpetiformis, and chronic
15 progressive multiple sclerosis. Also included are disorders or infections that impair mononuclear phagocyte function, for example, influenza virus infection and AIDS.

Monocyte associated disorders include monocytoses such as, for example, monocytoses associated with certain infections such as tuberculosis, brucellosis, subacute bacterial endocarditis, Rocky Mountain spotted fever, malaria, and visceral
20 leishmaniasis (kala azar), in malignancies, leukemias, myeloproliferative syndromes, hemolytic anemias, chronic idiopathic neutropenias, and granulomatous diseases such as sarcoidosis, regional enteritis, and some collagen vascular diseases.

Other monocyte associated disorders include monocytopenias such as, for example, monocytopenias that can occur with acute infections, with stress, following
25 administration of glucocorticoids, aplastic anemia, hairy cell leukemia, and acute myelogenous leukemia and as a direct result of administration of myelotoxic and immunosuppressive drugs.

Eosinophil associated disorders include eosinophilias such as, for example, eosinophilias that result from or accompany conditions such as allergic disorders,

infections caused by parasites and other organisms, dermatologic diseases, pulmonary diseases, collagen vascular disease, neoplasms, immunodeficiency diseases, gastroenteritis, inflammatory bowel disease, chronic active hepatitis, pancreatitis, and hypopituitarism. Also included are hypereosinophilic syndrome (HES) and chronic
5 and acute eosinophilic leukemias.

Other eosinophil associated disorders include eosinopenias such as, for example, eosinopenias that occur with stress, such as acute bacterial infection, and following administration of glucocorticoids.

Basophil associated disorders include basophilias such as, for example,
10 basophilias seen in myeloproliferative disorders (e.g., chronic myeloid leukemia, polycythemia vera, and myeloid metaplasia), following splenectomy, hemolytic anemia, ulcerative colitis, varicella infection, and Hodgkin's disease.

As TANGO 457 is expressed in the placenta, TANGO 457 nucleic acids, proteins, and modulators thereof can be used to modulate the proliferation, migration,
15 morphology, differentiation, and/or function of cells that form the placenta, e.g., the decidual cells (which arise during pregnancy), and thus can be used to treat placental disorders, such as toxemia of pregnancy (e.g., preeclampsia and eclampsia), placentitis, or spontaneous abortion.

As TANGO 457 is expressed in B-cell, chronic lymphocytic leukemia, TANGO
20 457 nucleic acids, proteins, and modulators thereof can be used to modulate the proliferation, migration, morphology, differentiation, and/or function of immune cells, e.g. B-cells, dendritic cells, natural killer cells and monocytes. TANGO 457 nucleic acids, proteins and modulators thereof can also be utilized to modulate immunoglobulins and formation of antibodies, and immune-related processes, e.g., the
25 host immune response.

Such TANGO 457 compositions and modulators thereof can be utilized modulate or treat immune disorders that include, but are not limited to, immune proliferative disorders (e.g., carcinoma, lymphoma, e.g., follicular lymphoma), disorders associated with fighting pathogenic infections (e.g., bacterial, such as

chlamydial, infection, parasitic infection, and viral infections such as HSV or HIV infections), pathogenic disorders associated with immune disorders (e.g., immunodeficiency disorders, such as HIV), autoimmune disorders (e.g., rheumatoid and juvenile arthritis, rheumatism, systemic lupus erythematosus, graft or allograft rejection, multiple sclerosis, Grave's disease, and Hashimoto's disease), immunodeficiency disorders (e.g., B and T cell immunodeficiency disorders and AIDS), bacterial, viral, and parasitic infections (e.g., sepsis, influenza, common colds, hepatitis, HIV infection, malaria, and gonorrhea), disorders associated with undesirable immune reactions with foreign material (e.g., transplant rejection, environmental {e.g., latex} hypersensitivity disorders, and allergic disorders), phagocytic dysfunction disorders (e.g., neutropenia and chronic granulomatous disease), anaphylaxis, urticaria, and inflammatory disorders (e.g., septicemia, cerebral malaria, inflammatory bowel disease, arthritis such as rheumatoid arthritis and osteoarthritis, allergic inflammatory disorders such as asthma and psoriasis, apoptotic disorders such as rheumatoid arthritis, systemic lupus erythematosus, and insulin-dependent diabetes mellitus, cytotoxic disorders, septic shock, and cachexia).

As TANGO 457 contains one or more Ig domains, and as immunoglobulin superfamily proteins are cell surface molecules involved in signal transduction and cellular proliferation, TANGO 457 nucleic acids, proteins and modulators thereof can be utilized to modulate the development and progression of cancerous and non-cancerous cell proliferative disorders, such as deregulated proliferation (such as hyperdysplasia, hyper-IgM syndrome, or lymphoproliferative disorders), cirrhosis of the liver (a condition in which scarring has overtaken normal liver regeneration processes), treatment of keloid (hypertrophic scar) formation (disfiguring of the skin in which the scarring process interferes with normal renewal), psoriasis (a common skin condition characterized by excessive proliferation of the skin and delay in proper cell fate determination), benign tumors, fibrocystic conditions, and tissue hypertrophy (e.g., prostatic hyperplasia), cancers such as neoplasms or tumors (such as carcinomas, sarcomas, adenomas or myeloid lymphoma tumors, e.g., fibrosarcoma, myxosarcoma,

liposarcoma, chondrosarcoma, osteogenic sarcoma, chordoma, angiosarcoma, endotheliosarcoma, lymphangiosarcoma, lymphangioendotheliosarcoma, synovioma, mesothelioma, Ewing's tumor, leiomyosarcoma, rhabdotheriosarcoma, colon sarcoma, pancreatic cancer, breast cancer, ovarian cancer, prostate cancer, squamous cell carcinoma, basal cell carcinoma, adenocarcinoma, sweat gland carcinoma, sebaceous gland carcinoma, papillary carcinoma, papillary adenocarcinomas, cystadenocarcinoma, medullary carcinoma, bronchogenic carcinoma, renal cell carcinoma, hematoma, bile duct carcinoma, melanoma, choriocarcinoma, seminoma, embryonal carcinoma, Wilms' tumor, cervical cancer, testicular tumor, lung carcinoma, small cell carcinoma, bladder carcinoma, epithelial carcinoma, glioma, astrocytoma, medulloblastoma, craniopharyngioma, ependynoma, pinealoma, hemangioblastoma, retinoblastoma), leukemias, (e.g. acute lymphocytic leukemia), acute myelocytic leukemia (myeloblastic, promyelocytic, myelomonocytic, monocytic and erythroleukemia), chronic leukemias (chronic myelocytic (granulocytic) leukemia and chronic lymphocytic leukemia), or polycythemia vera, or lymphomas (Hodgkin's disease and non-Hodgkin's diseases), multiple myelomas and Waldenström's macroglobulinemia.

TANGO 229

A cDNA clone (designated jthtc001c06) encoding at least a portion of human TANGO 229 protein was isolated from a human T cell cDNA library. Human TANGO 229 protein is a transmembrane protein.

The full length of the cDNA encoding human TANGO 229 protein (Figure 10; SEQ ID NO: 71) is 3594 nucleotide residues. The open reading frame (ORF) of this cDNA, nucleotide residues 72 to 2216 of SEQ ID NO: 71 (i.e., SEQ ID NO: 72), encodes a 715-amino acid residue protein (Figure 10; SEQ ID NO: 73), corresponding to a 681-residue transmembrane mature protein.

The invention thus includes purified human TANGO 229 protein, both in the form of the immature 715 amino acid residue protein (SEQ ID NO: 73) and in the

form of the mature 681 amino acid residue protein (SEQ ID NO: 75). Mature human TANGO 229 proteins can be synthesized without the signal sequence polypeptide at the amino terminus thereof, or they can be synthesized by generating immature TANGO 229 protein and cleaving the signal sequence therefrom.

5 The invention includes nucleic acid molecules which encode a polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the nucleotide sequence listed in SEQ ID NO: 71, such as the portion which encodes mature TANGO 229 protein, immature TANGO 229 protein, or a domain of TANGO 229 protein. These nucleic acids are collectively referred to as nucleic
10 acids of the invention.

TANGO 229 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional features.

A common domain present in TANGO 229 proteins is a signal sequence. In one embodiment, a TANGO 229 protein contains a signal sequence corresponding to
15 amino acid residues 1 to 34 of SEQ ID NO: 73 (SEQ ID NO: 74). It is recognized that the carboxyl terminal boundary of the signal sequence can be located one or two residues from the residue identified above (i.e., following residues 32, 33, 34, 35, or 36 of SEQ ID NO: 73). The signal sequence is cleaved during processing of the mature protein.

20 TANGO 229 proteins include a transmembrane domain and two extra-membrane domains flanking the cell membrane. The transmembrane domain corresponds to about amino acid residues 456 to 480 of SEQ ID NO: 73 (i.e., the transmembrane domain having the sequence SEQ ID NO: 77). One of the extra-membrane domains corresponds to about amino acid residues 35 to 455 of SEQ ID
25 NO: 73. This domain has the sequence SEQ ID NO: 76, and is most likely an extracellular domain. The other extra-membrane domain corresponds to about amino acid residues 481 to 715 of SEQ ID NO: 73. This domain has the sequence SEQ ID NO: 78, and is most likely a cytoplasmic domain. In one embodiment, the domain corresponding to about amino acid residues 35 to 455 of SEQ ID NO: 73 is a

cytoplasmic domain, and the domain corresponding to about amino acid residues 481 to 715 is an extracellular domain.

TANGO 229 proteins typically comprise a variety of potential post-translational modification sites and protein domains (often positioned within an extracellular domain), such as those described herein in Table II, as predicted by computerized sequence analysis of TANGO 229 proteins using amino acid sequence comparison software (comparing the amino acid sequence of TANGO 229 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}).

CUB domain	41 to 147	See Fig. 10
Factor V/VIII discoidin domain	258 to 409	See Fig. 10

In various embodiments, the protein of the invention has at least 1, 2, 4, 6, 10,
5 15, or 20 or more of the post-translational modification sites described herein in
Table II.

Examples of additional domains present in human TANGO 229 protein
include a CUB domain and a Factor V/VIII discoidin domain. In one embodiment,
the protein of the invention has at least one domain or signature sequence that is at
10 least 55%, preferably at least about 65%, 75%, 85%, or 95% identical to one of the

domains or signature sequences described herein in Table II. Preferably, the protein of the invention has at least one CUB domain and one Factor V/VIII discoidin domain.

CUB domains are extracellular domains of about 110 amino acid residues which occur in functionally diverse, mostly developmentally regulated proteins (Bork and Beckmann (1993) *J. Mol. Biol.* 231:539-545; Bork (1991) *FEBS Lett.* 282:9-12). Many CUB domains contain four conserved cysteine residues, although some, like that of TANGO 202, contain only two of the conserved cysteine residues. The structure of the CUB domain has been predicted to assume a beta-barrel configuration, similar to that of immunoglobulins. Other proteins which comprise one or more CUB domains include, for example, mammalian complement sub-components C1s and C1r, hamster serine protease Casp, mammalian complement activating component of Ra-reactive factor, vertebrate enteropeptidase, vertebrate bone morphogenic protein 1, sea urchin blastula proteins BP10 and SpAN, *Caenorhabditis elegans* hypothetical proteins F42A10.8 and R151.5, neuropilin (A5 antigen, in which a pair of Factor V/VIII discoidin domains also occur), sea urchin fibropellins I and III, mammalian hyaluronate-binding protein TSG-6 (PS4), mammalian spermadhesins, and *Xenopus* embryonic protein UVS.2. The presence of a CUB domain in TANGO 229 protein indicates that TANGO 229 is involved in one or more physiological processes in which these other CUB domain-containing proteins are involved, has a biological activity in common with one or more of these other CUB domain-containing proteins, or both. The presence of a CUB domain in TANGO 229 protein also indicates that TANGO 229 can be developmentally regulated.

Factor V/VIII discoidin domains are involved in binding with cell surface-attached carbohydrates. These domains occur in a variety of intracellular, extracellular, and transmembrane proteins, including human and murine coagulation factor V, human and murine coagulation factor VIII precursor, human and murine neuropilins, a variety of receptor-like tyrosine kinases (e.g., neurotrophic tyrosine

kinases and cell adhesion tyrosine kinases), carboxypeptidases and carboxypeptidase-like proteins, milk fat globule glycoproteins, human breast epithelial antigen BA46, murine neuroligin IV, human X-linked juvenile retinoschisis precursor protein, and human contactin associated protein. Presence of a Factor

5 V/VIII discoidin domain in TANGO 229 indicates that this protein is involved in one or more physiological processes in which these other Factor V/VIII discoidin domain-containing proteins are involved, has biological activity in common with one or more of these other Factor V/VIII discoidin domain-containing proteins, or both. Presence of a Factor V/VIII discoidin domain in TANGO 229 protein is an

10 indication that TANGO 229 is associated with binding of one or more glycosylated proteins at the surface of cells which express TANGO 229. Binding of glycosylated proteins at the cell surface is associated with several physiologically relevant phenomena, including cell adhesion (including cell repulsion), transmembrane signal transduction, and nutrient binding and uptake by cells. The Factor V/VIII discoidin

15 domain of human coagulation factor VIII protein is known to be involved in binding of factor VIII with von Willebrand factor and with membrane-associated lipids such as phosphatidylserine. Presence of a Factor V/VIII discoidin domain in TANGO 229 protein is thus an indication that the extracellular portion of TANGO 229 protein can interact with membrane lipids.

20 The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that human TANGO 229 protein includes a 34 amino acid residue signal peptide (amino acid residues 1 to 34 of SEQ ID NO: 73; SEQ ID NO: 74) preceding the mature TANGO 229 protein (amino acid residues 35 to 715 of SEQ ID NO: 73; SEQ ID NO: 75). Human TANGO 229 protein includes

25 an extracellular domain (amino acid residues 35 to 455 of SEQ ID NO: 73; SEQ ID NO: 76), a transmembrane domain (amino acid residues 456 to 480 of SEQ ID NO: 73; SEQ ID NO: 77), and an intracellular domain (amino acid residues 481 to 715 of SEQ ID NO: 73; SEQ ID NO: 78). In an alternative embodiment, amino acid residues 35 to 455 of SEQ ID NO: 73 correspond to an intracellular domain of

human TANGO 229 protein and residues 481 to 715 correspond to an extracellular domain.

Figure 10G depicts a hydrophobicity plot of human TANGO 229 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to 34 of SEQ ID NO: 73 is the signal sequence of human TANGO 229 (SEQ ID NO: 74). As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human TANGO 229 protein from about amino acid residue 50 to about amino acid residue 70 appears to be located at or near the surface of the protein, while the region from about amino acid residue 195 to about amino acid residue 210 appears not to be located at or near the surface.

The predicted molecular weight of human TANGO 229 protein without modification and prior to cleavage of the signal sequence is about 77.9 kilodaltons. The predicted molecular weight of the mature human TANGO 229 protein without modification and after cleavage of the signal sequence is about 72.3 kilodaltons.

Northern hybridization experiments using human tissue samples indicated that mRNA corresponding to cDNA encoding TANGO 229 is expressed in the tissues listed in Table IIIA, wherein "++" indicates strongly detectable expression, "+" indicates a lesser degree of expression, and "+/-" indicates a still lesser degree of expression. In these tissues, two alternatively spliced forms of cDNA encoding TANGO 229 (having sizes of about 2.0 and 4.0 kilobases) were detected.

Table IIIA

Tissue	Expression
Heart	++
Liver	++
Pancreas	++
Placenta	+
Brain	+/-
Lung	+/-
Skeletal Muscle	+/-
Kidney	+/-

Northern hybridization experiments using human immune system tissue samples indicated that mRNA corresponding to the cDNA encoding TANGO 229 is expressed in the tissues listed in Table IIIB. In these tissues, two alternatively spliced forms of cDNA encoding TANGO 229 (having sizes of about 2.0 and 4.9 kilobases) were detected.

Table IIIB

Tissue	Expression
Spleen	++
Lymph node	++
Fetal Liver	++
Peripheral blood leukocytes	+
Bone Marrow	+
Thymus	+/-

The nucleotide sequence (SEQ ID NO: 71) of TANGO 229 cDNA was aligned (using the LALIGN software {Huang and Miller (1991) Adv. Appl. Math. 12:373-381}); pam120 scoring matrix, gap opening penalty = 12, gap extension

penalty = 4) with the nucleotide sequence of the portion of human chromosome region 6q21 listed in GenBank Accession No. Z85999. This alignment indicated 45.8% identity between the two sequences in the 3826-residue overlapping portion. The nucleotide sequence (SEQ ID NO: 71) of TANGO 229 cDNA was also aligned (using the LALIGN software; pam120 scoring matrix, gap opening penalty = 12, gap extension penalty = 4) with an expressed sequence tag (EST) clone designated BP481 in P.C.T. Publication No. WO98/45435. This alignment indicated 72.9% identity between the two sequences in the 414-residue overlapping portion.

10 Uses of TANGO 229 Nucleic acids,
 Polypeptides, and Modulators Thereof

TANGO 229 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not expressed. Based on the observations that cDNA corresponding to TANGO 229 occurs in a human T cell cDNA library, and that RNA corresponding to TANGO 229 is detectable by Northern analysis of human heart, liver, pancreas, placenta, brain lung, skeletal muscle, kidney, spleen, lymph node, peripheral blood leukocyte, bone marrow, and thymus tissues, it is evident that TANGO 229 protein can be involved in one or more biological processes which occur in these tissues. In particular, TANGO 229 can be involved in modulating growth, proliferation, survival, differentiation, and activity of cells of these tissues (e.g., T cells and other cells of the immune system).

Expression of TANGO 229 in a variety of immune system tissues (e.g., T cells, peripheral blood leukocyte, and spleen, lymph node, bone marrow, and thymus tissues) is an indication that TANGO 229 can have a role in both normal immune processes and in a variety of disorders which affect or involve the immune system, such as the immune disorders described elsewhere in this disclosure.

The presence of a factor V/VIII discoidin domain in TANGO 229 protein is an indication that the protein can be involved in mediating cell binding and adhesion,

including binding / adhesion of cells with other cells, with extracellular matrix, and with foreign materials (i.e., materials not originating in the body of the same individual). Cell binding and adhesion affected by TANGO 229 can encompass interactions between cells and between cells and extracellular components, which
5 interactions lend structural and mechanical support to body tissues and containment of body fluids (e.g., by blood coagulation). However, TANGO 229 can also regulate cell-to-cell and cell-to-environment interactions which have little relevance to the structural integrity of the animal, but which permit information exchange between cells (e.g., cell-to-cell signaling such as that which occurs between helper T cells and
10 antibody-producing B cells) or between cells and the environment (e.g., recognition by cells of the presence of a particular chemical entity, such as an antigen, in the environment). Certain cell-to-environment interactions mediated by TANGO 229 can also permit a cell which expresses it to exert an effect upon (e.g., degrade, absorb, or envelop) a component of the environment.

15 Involvement of TANGO 229 protein in binding of cells is an indication that TANGO 229 can be involved in disorders associated with aberrant binding or adhesion of cells with other cells, with extracellular matrix, or with foreign materials. Disorders involving aberrant binding or adhesion of cells with other cells include both disorders in which cells normally bind with one another (e.g., metastasis of
20 normally solid tumor tissue cells away from the tumor site of origin or immune hypersensitivity) and disorders in which the cells do not normally bind with one another, but do bind with one another in individuals afflicted with the disorder (e.g., metastasis of tumor cells into a tissue in which the cells do not normally occur, autoimmune disorders, infections, wherein cells with which T cells bind are not
25 normally present in the animal, or disorders associated with abnormal blood coagulation). Disorders involving aberrant binding or adhesion of cells with extracellular matrix include those (e.g., metastasis of cancerous cells through or into extracellular matrix and away from the normal body location of the cells) in which the cells normally do, but aberrantly do not, bind with extracellular matrix as well as

those (e.g., metastasis of cancers cells into extracellular matrix at body locations at which they do not normally occur, autoimmune disorders, liver fibrosis, abnormal blood coagulation, atherosclerosis, and arteriosclerosis) in which the cells normally do not bind with extracellular matrix, but aberrantly do. Examples of disorders
5 involving aberrant binding or adhesion of cells with foreign materials include those (e.g., allergies and hypersensitivity disorders such as latex hypersensitivity) associated with aberrant binding with the foreign material and disorders in which the cells normally bind with the foreign material, but aberrantly do not. TANGO 229 proteins, nucleic acids encoding them, and agents that modulate activity or
10 expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

Like certain known developmental proteins (e.g., human neuropilins; Kolodkin and Ginty (1997) Neuron 19:1159-1162), TANGO 229 protein contains both a CUB domain and a factor V/VIII discoidin domain. The presence of both of
15 these types of domains is an indication that TANGO 229 protein is involved in mediating attraction and repulsion of cells and translocation of cells through, past, or along other cells or tissues. For example, TANGO 229 can, alone or in conjunction with one or more neuropilins, bind with a semaphorin protein to direct nerve growth. Apart from regulating the rate and direction of nerve growth, TANGO 229 can
20 regulate the rate and direction of growth of other tissues, such as vascular tissues (e.g., during angiogenesis). TANGO 229 can also modulate the direction and rate of cell movement, relative to another cell or relative to a tissue, such as movement of leukocytes through vascular luminal epithelium (e.g., during leukocytic extravasation) or movement of metastatic cells through a solid tissue. Another
25 example of such modulation is the effect that TANGO 229 can have on the rate of cell growth, depending on contact between two cells or between two tissues. TANGO 229 can regulate cell growth such that the growth slows or substantially stops when two tissues contact one another (e.g., during wound healing). TANGO 229 is thus involved in disorders associated with aberrant growth or movement of

cells through, past, or along other cells or tissues. Examples of disorders of these types include cancerous growth and proliferation of cells, metastasis of cancerous cells (i.e., including metastasis away from the normal body location of the cells, through tissues and extracellular matrix, and into body locations at which the cells do not normally occur), inflammation, atherosclerosis, arteriosclerosis, abnormal blood coagulation, asthma, and chronic obstructive pulmonary disorders. TANGO 229 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

Like many transmembrane signaling proteins, TANGO 229 protein comprises extracellular domains capable of interacting with environmental cues (e.g., the presence or absence of particular cells, proteins, or small molecules) and a cytoplasmic domain having a substantial size. For example, several tyrosine-protein kinases (e.g., human and murine cell adhesion kinase and neurotrophic receptor-related tyrosine kinase-3) comprise one or more factor V/VIII discoidin domains. The structure of TANGO 229 protein, which has several potential phosphorylation sites, is thus an indication that the protein can be involved in transducing signals across the cell membrane. Binding of a ligand of TANGO 229 protein with a portion of the protein located on one side of the membrane can affect one or more characteristics (e.g., conformation, phosphorylation state, or level or specificity of enzymatic activity) of a portion of the protein located on the other side. Thus, for example, a compound in the extracellular environment of a cell which expresses TANGO 229 can bind with the extracellular domain of the protein, thereby effecting a change in a characteristic of the intracellular portion of the protein, leading to alteration of the physiology of the cell (e.g., effected by an activity exerted by the intracellular portion of the protein on another component of the cell). The compound in the extracellular environment can, for example, be a compound dissolved or suspended in a liquid, a compound attached to another cell of the same animal, or a compound attached to a foreign cell or virus particle. TANGO 229 protein can

associate with other signal transduction proteins in the cell membrane, thereby modulating the intracellular activity of those other proteins. TANGO 229 protein can thus have a role in disorders which involve aberrant transmembrane signal transduction. Examples of signal transduction-related disorders include cystic
5 fibrosis, various chronic obstructive pulmonary disorders, inflammation, aberrant or undesirable angiogenesis, and obesity. TANGO 229 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

10 INTERCEPT 289

A cDNA clone (designated jthLa186d06) encoding at least a portion of human INTERCEPT 289 protein was isolated from a human mixed lymphocyte reaction cDNA library. Human INTERCEPT 289 protein is a transmembrane protein which can occur in at least six alternative forms. These forms are herein
15 designated "form 1a," "form 1b," "form 2a," "form 2b," "form 3a," and "form 3b" for convenience. The properties of and variations among these forms are described herein.

1a) The full length of the cDNA encoding INTERCEPT 289 protein form 1a (Figures 11A-11C and SEQ ID NO: 81) is 4074 nucleotide residues. The ORF of
20 this cDNA, nucleotide residues 179 to 742 of SEQ ID NO: 81 (i.e., SEQ ID NO: 82), encodes a 188-amino acid residue protein having the amino acid sequence SEQ ID NO: 83.

1b) The full length of the cDNA encoding INTERCEPT 289 protein form 1b (Figures 11D-11G and SEQ ID NO: 91) is 4018 nucleotide residues. The ORF of
25 this cDNA, nucleotide residues 179 to 712 of SEQ ID NO: 91 (i.e., SEQ ID NO: 92), encodes a 178-amino acid residue protein having the amino acid sequence SEQ ID NO: 93.

2a) The full length of the cDNA encoding INTERCEPT 289 protein form 2a (Figures 11H-11K and SEQ ID NO: 96) is 3985 nucleotide residues. The ORF of

this cDNA, nucleotide residues 162 to 656 of SEQ ID NO: 96 (i.e., SEQ ID NO: 97), encodes a 165-amino acid residue protein having the amino acid sequence SEQ ID NO: 98.

2b) The full length of the cDNA encoding INTERCEPT 289 protein form 2b (Figures 11L-11O and SEQ ID NO: 101) is 3958 nucleotide residues. The ORF of this cDNA, nucleotide residues 162 to 626 of SEQ ID NO: 101 (i.e., SEQ ID NO: 102), encodes a 155-amino acid residue protein having the amino acid sequence SEQ ID NO: 103.

3a) The full length of the cDNA encoding INTERCEPT 289 protein form 3a (Figures 11P-11S and SEQ ID NO: 106) is 3925 nucleotide residues. The ORF of this cDNA, nucleotide residues 162 to 596 of SEQ ID NO: 106 (i.e., SEQ ID NO: 107), encodes a 145-amino acid residue protein having the amino acid sequence SEQ ID NO: 108.

3b) The full length of the cDNA encoding INTERCEPT 289 protein form 3b (Figures 11T-11V and SEQ ID NO: 111) is 3898 nucleotide residues. The ORF of this cDNA, nucleotide residues 162 to 566 of SEQ ID NO: 111 (i.e., SEQ ID NO: 112), encodes a 135-amino acid residue protein having the amino acid sequence SEQ ID NO: 113.

The mixed lymphocyte reaction library from which the cDNAs encoding INTERCEPT 289 were isolated was prepared as follows. Mononuclear cells were isolated from 50 milliliters of peripheral blood pooled from 22 human donors. Mononuclear cells were isolated using HISTOPAQUE™ 1077 (Sigma Chemical Co., St. Louis, MO) according to the manufacturer's instructions and collected in heparinized tubes. After pooling the mononuclear cells, CD19⁺ B cells were removed by positive selection using MACS™ beads and a VS+ separation column (Miltenyi Biotec, Germany) according to the manufacturer's instructions. CD19⁻ cells were re-suspended at an approximate density of 10×10^6 cells per milliliter in RPMI medium supplemented with 10% (v/v) fetal bovine serum, antibiotics, and L-glutamine. The cells were maintained at 37°C in a humidified incubator, and were

harvested 4, 14, and 24 hours following re-suspension. Total RNA was isolated from the cells by guanidinium isothiocyanate / beta-mercaptoethanol lysis followed by cesium chloride gradient centrifugation. Isolated RNA was treated with DNase, and the poly-A-containing fraction of total RNA was further purified using
5 OLIGOTEX™ beads (Qiagen, Inc.). About 4.4 micrograms of poly-A-containing RNA was used to synthesize a cDNA library using the Superscript™ cDNA synthesis kit (Gibco BRL, Inc.; Gaithersburg, MD). cDNA was directionally cloned into expression plasmid pMET7 vectors using Sall and NotI polylinker restriction endonuclease sites in order to generate a plasmid library. Transformants were
10 randomly selected and expanded in culture for single-pass nucleotide sequencing.

The invention includes nucleic acid molecules which encode a polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the nucleotide sequence listed in one of SEQ ID NOs: 81, 91, 96, 101, 106, and 111, such as the portion which encodes INTERCEPT 289 protein or a domain (e.g., the
15 extracellular domain) of INTERCEPT 289 protein. These nucleic acids are collectively referred to as nucleic acids of the invention.

In each form, INTERCEPT 289 protein includes a transmembrane domain and a portion corresponding to an extra-membrane (presumably extracellular) domain. In alternative embodiments, this extra-membrane domain is a cytoplasmic
20 domain. The transmembrane domain corresponds to about amino acid residues 7 to 27 of SEQ ID NO: 83 (i.e., SEQ ID NO: 84 in form 1a), to about amino acid residues 7 to 27 of SEQ ID NO: 93 (i.e., SEQ ID NO: 94 in form 1b), to about amino acid residues 7 to 27 of SEQ ID NO: 98 (i.e., SEQ ID NO: 99 in form 2a), to about amino acid residues 7 to 27 of SEQ ID NO: 103 (i.e., SEQ ID NO: 104 in form 2b), to
25 about amino acid residues 7 to 28 of SEQ ID NO: 108 (i.e., SEQ ID NO: 109 in form 3a), and to about amino acid residues 7 to 28 of SEQ ID NO: 113 (i.e., SEQ ID NO: 114 in form 3b).

Each form of INTERCEPT 289 protein also includes another extra-membrane portion. This portion corresponds to about amino acid residues 28 to 188

of SEQ ID NO: 83 (i.e., SEQ ID NO: 85 in form 1a), to about amino acid residues 28 to 178 of SEQ ID NO: 93 (i.e., SEQ ID NO: 95 in form 1b), to about amino acid residues 28 to 165 of SEQ ID NO: 98 (i.e., SEQ ID NO: 100 in form 2a), to about amino acid residues 28 to 155 of SEQ ID NO: 103 (i.e., SEQ ID NO: 105 in form 2b), to about amino acid residues 29 to 145 of SEQ ID NO: 108 (i.e., SEQ ID NO: 110 in form 3a), and to about amino acid residues 29 to 135 of SEQ ID NO: 113 (i.e., SEQ ID NO: 115 in form 3b).

INTERCEPT 289 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional features, as illustrated in Figures 11W and 11X-1 through 11X-14.

In Figure 11W, the amino acid sequences of various forms of INTERCEPT 289 ("A"-F"; SEQ ID NOs: 83, 93, 98, 103, 108, and 113) are shown, as aligned using the Wisconsin™ BestFit software (Smith and Waterman, (1981) Adv. Appl. Math. 2:482-489; blosum62 scoring matrix; gap opening penalty 10 / gap extension penalty 10). In Figures 11X-1 through 11X-14, the nucleotide sequences (SEQ ID NOs: 81, 91, 96, 101, 106, and 111) of cDNA molecules encoding the six forms of INTERCEPT 289 protein described herein are aligned using the Wisconsin™ BestFit software (Smith and Waterman, (1981) Adv. Appl. Math. 2:482-489; gap opening penalty 10 / gap extension penalty 10). As indicated in these figures, the various forms of INTERCEPT 289 protein differ in the length of the polypeptide sequence between the transmembrane domain and the lectin C-type domain described below and in the amino acid sequence of the carboxyl-terminal portion of the protein.

INTERCEPT 289 proteins typically comprise a variety of potential post-translational modification sites and protein domains (often positioned within a domain located at or near the protein surface), such as those described herein in Table IVA, as predicted by computerized sequence analysis of INTERCEPT 289 proteins using amino acid sequence comparison software (comparing the amino acid sequence of INTERCEPT 289 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}).

Table IVA

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: ## (INTERCEPT 289 form)						Amino Acid Sequence

In various embodiments, the protein of the invention has at least 1, 2, 4, 6, 8,
5 12, or more of the post-translational modification sites and domains described in
Table IVA.

An example of an additional domain present in INTERCEPT 289 proteins is
a lectin C-type domain. In one embodiment, the protein of the invention has at least
one domain or signature sequence that is at least 55%, preferably at least about 65%,

75%, 85%, or 95% identical to this domain. C-type lectin domains are conserved among proteins (e.g., animal lectins) which are involved in calcium-dependent binding of carbohydrates, although it has recently been recognized that these domains can also be involved in binding of proteins (Drickamer, (1988) J. Biol. Chem. 263:9557-9560; Drickamer, (1993) Prog. Nucl. Acid Res. Mol. Biol. 45:207-232; Drickamer, (1993) Curr. Opin. Struct. Biol. 3:393-400). C-type lectins and their relevant properties are described in greater in P.C.T. Publication No. WO 98/28332, which, as with all references cited herein, is incorporated by reference.

A cDNA clone (designated jtmMa127f05) encoding at least a portion of murine INTERCEPT 289 protein was also isolated. Murine INTERCEPT 289 protein is a transmembrane protein. The properties of murine INTERCEPT 289 are described below.

Murine INTERCEPT 289 protein includes a transmembrane domain and a portion corresponding to an extra-membrane domain. In one embodiment, the domain is extracellular; in an alternative embodiments, this extra-membrane domain is a cytoplasmic domain. The transmembrane domain corresponds to about amino acid residues 7 to 27 of SEQ ID NO: 163 (i.e., SEQ ID NO: 164), and the extra-membrane portion corresponds to about amino acid residues 28 to 190 of SEQ ID NO: 163 (i.e., SEQ ID NO: 165).

Murine INTERCEPT 289 proteins typically comprise a variety of potential post-translational modification sites and protein domains (often positioned within a domain located at or near the protein surface), such as those described herein in Table IVB, as predicted by computerized sequence analysis of murine INTERCEPT 289 protein using amino acid sequence comparison software (comparing the amino acid sequence of murine INTERCEPT 289 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}).

Table IVB

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 163	Amino Acid Sequence
N-glycosylation site	51 to 54	NVSQ
	146 to 149	NNSV
	153 to 156	NVTN
Protein kinase C phosphorylation site	180 to 182	SYR
Casein kinase II phosphorylation site	88 to 91	SFSE
	155 to 158	TNQD
N-myristoylation site	105 to 110	GSTLAI
	152 to 157	GNVTNQ
	167 to 172	GLTKTY
Lectin C-type domain	99 to 185	See Fig. 11

In various embodiments, the protein of the invention has at least 1, 2, 4, 6, 8, or more of the post-translational modification sites and domains described in Table IVB.

INTERCEPT 289 proteins and cDNAs exhibit homology with human myeloid DAP12 (DNAX accessory protein, 12 kilodalton) associated lectin-1 (MDL-1), which is described in PCT Publication No. WO 99/06557, which is also incorporated herein by reference. In Figure 11W, the amino acid sequences of various forms of INTERCEPT 289 ("A"- "F" and "R"; SEQ ID NOs: 83, 93, 98, 103, 108, 113, and 163, respectively), human MDL-1 ("H"; SEQ ID NO: 86), and murine MDL-1 ("M"; SEQ ID NO: 88) proteins are shown, as aligned using the Wisconsin™ BestFit software (Smith and Waterman, (1981) Adv. Appl. Math. 2:482-489; BLOSUM62 scoring matrix; gap opening penalty 10 / gap extension penalty 10). Each of the seven forms of INTERCEPT 289 protein described herein has a lysine residue (i.e., at residue 116 of SEQ ID NOs: 83 and 93, at residue 93 of

SEQ ID NOs: 98 and 103, at residue 73 of SEQ ID NOs: 108 and 113, and at residue 118 of SEQ ID NO: 163) that is not present in the described sequence (SEQ ID NO: 86) of human MDL-1 protein.

5 In the alignment shown in Figure 11W, the amino acid sequence (SEQ ID NO: 83) of form 1a of INTERCEPT 289 protein is 100% identical to that of human MDL-1 over the 187-amino acid residue overlapping region and about 72.7% identical to that of murine MDL-1 in the 165-amino acid residue overlapping region.

10 In the alignment shown in Figure 11W, the amino acid sequence (SEQ ID NO: 93) of form 1b of INTERCEPT 289 protein is about 85.9% identical to that of human MDL-1 over the 177-amino acid residue overlapping region and about 60.0% identical to that of murine MDL-1 in the 155-amino acid residue overlapping region.

15 In the alignment shown in Figure 11W, the amino acid sequence (SEQ ID NO: 98) of form 2a of INTERCEPT 289 protein is 100% identical to that of human MDL-1 over the 164-amino acid residue overlapping region and about 71.5% identical to that of murine MDL-1 in the 165-amino acid residue overlapping region.

In the alignment shown in Figure 11W, the amino acid sequence (SEQ ID NO: 103) of form 2b of INTERCEPT 289 protein is about 83.8% identical to that of human MDL-1 over the 154-amino acid residue overlapping region and about 58.7% identical to that of murine MDL-1 in the 155-amino acid residue overlapping region.

20 In the alignment shown in Figure 11W, the amino acid sequence (SEQ ID NO: 108) of form 3a of INTERCEPT 289 protein is about 83.3% identical to that of human MDL-1 over the 144-amino acid residue overlapping region and about 74.5% identical to that of murine MDL-1 in the 145-amino acid residue overlapping region.

25 In the alignment shown in Figure 11W, the amino acid sequence (SEQ ID NO: 113) of form 3b of INTERCEPT 289 protein is about 63.4% identical to that of human MDL-1 over the 134-amino acid residue overlapping region and about 60.0% identical to that of murine MDL-1 in the 135-amino acid residue overlapping region.

In the alignment shown in Figure 11W, the amino acid sequence (SEQ ID NO: 163) of murine INTERCEPT 289 protein is 100% identical to that of murine

MDL-1 over the 190-amino acid residue overlapping region and about 85.7% identical to that of human MDL-1 in the 188-amino acid residue overlapping region.

In the alignment shown in Figure 11Z-5, the nucleotide sequence (SEQ ID NO: 162) of the ORF of murine INTERCEPT 289 is about 71.8% identical to that of the ORF of human INTERCEPT 289 form 1a.

MDL-1 is a cell surface protein which is expressed by monocytes and macrophages and which binds with DAP12. DAP12 is a cell surface protein which is expressed by natural killer cells, peripheral blood granulocytes and monocytes, macrophages, and dendritic cells. DAP12 is an immunoreceptor tyrosine-based activation motif-containing protein which associates non-covalently with activating isoforms of MHC class I receptors on natural killer cells (Bakker et al., 1999, Proc. Natl. Acad. Sci. USA 96:9792-9796). Association of MDL-1 and DAP12 on the surface of monocytes and macrophages and binding of associated MDL-1 / DAP12 with a ligand thereof (e.g., a surface protein, glycoprotein, or glycolipid on the surface of another cell of the same animal or on the surface of a foreign cell) causes activation of those cells. Upon activation, and depending on the type of the monocyte / macrophage, the monocyte / macrophage generates an oxidative burst, produces one or more cytokines, and other leukocyte-modulating molecules, releases one or more cytokines other leukocyte-modulating molecules, or some combination of these activities. MDL-1 and, by analogy, INTERCEPT 289 are therefore involved in modulation of immune function, including modulation of antibody and cytotoxic T cell responses, expansion of immune cell populations, inflammation, and generation of memory B cells.

The amino acid sequences (SEQ ID NOs: 83, 93, 98, 103, 108, and 113) of the six forms of INTERCEPT 289 protein described herein were aligned with the amino acid sequence of CD94 protein (GenBank Accession No. 5542082) using the Wisconsin™ BestFit software (Smith and Waterman, (1981) Adv. Appl. Math. 2:482-489; BLOSUM62 scoring matrix; gap opening penalty 10 / gap extension penalty 10). The amino acid sequence identity between CD94 protein and

INTERCEPT 289 protein was 28.0% for form 1a in the 126-amino acid residue overlapping region, 25.2% for form 1b in the 115-amino acid residue overlapping region, 28.0% for form 2a in the 125-amino acid residue overlapping region, 25.2% for form 2b in the 127-amino acid residue overlapping region, 27.2% for form 3a in the 125-amino acid residue overlapping region, and 24.3% for form 3b in the 115-amino acid residue overlapping region. CD94 protein is a cell-surface protein which has a C-type lectin domain in its carboxyl terminal portion and which acts as a receptor for natural killer (NK) cells. CD94 modulates the cytotoxic activity of NK cells, as well as production of cytokines by NK cells.

10 Figures 11Y-1 through 11Y-6 depict hydrophobicity plots of the six forms of human INTERCEPT 289 protein described herein. Form 1a corresponds to Figure 11Y-1, and has the amino acid sequence SEQ ID NO: 83. Form 1b corresponds to Figure 11Y-2, and has the amino acid sequence SEQ ID NO: 93. Form 2a corresponds to Figure 11Y-3, and has the amino acid sequence SEQ ID NO: 98. Form 2b corresponds to Figure 11Y-4, and has the amino acid sequence SEQ ID NO: 103. Form 3a corresponds to Figure 11Y-5, and has the amino acid sequence SEQ ID NO: 108. Form 3b corresponds to Figure 11Y-6, and has the amino acid sequence SEQ ID NO: 113. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. Figure 11Z-6 depicts a hydrophobicity plot of the murine INTERCEPT 289 protein described herein.

25 The predicted molecular weights of the six forms of human INTERCEPT 289 protein described herein, without modification, is about 21.5 kilodaltons for form 1a, about 20.4 kilodaltons for form 1b, about 19.1 kilodaltons for form 2a, about 18.0 kilodaltons for form 2b, about 16.9 kilodaltons for form 3a, and about 15.8 kilodaltons for form 3b. The predicted molecular weight of murine INTERCEPT 289, without modification is about 21.7 kilodaltons.

Expression of one or more forms of INTERCEPT 289 was detected in cDNA libraries prepared using human tissue and cell samples listed in Table V, wherein "+" indicates detectable expression and "+/-" indicates weakly detectable expression.

Table V

cDNA library	Expression
Promyelocytic Leukemia Cells	+
Bone Marrow	+
D8 Dendritic Cells	+/-
Ovarian Ascites	+/-
Aortic Endothelial Cells	+/-
Congestive Heart Failure (left ventricle)	+/-

5

Uses of INTERCEPT 289 Nucleic acids, Polypeptides, and Modulators Thereof

INTERCEPT 289 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not
 10 expressed. Based on the observations that cDNA corresponding to INTERCEPT 289 occurs in a human mixed lymphocyte reaction cDNA library, and that RNA corresponding to INTERCEPT 289 is detectable by PCR amplification, using primers which specifically amplify INTERCEPT 289 sequences, of nucleic acids (e.g., mRNA or cDNA) obtained from human leukemia, bone marrow, dendritic,
 15 ovarian ascitic, aortic endothelial, and cardiac (e.g., left ventricle cells obtained from a heart afflicted with congestive heart failure) cells, it is evident that INTERCEPT 289 protein can be involved in one or more biological processes which occur in these cells and in tissues which contain them. In particular, INTERCEPT 289 is involved in modulating growth, proliferation, survival, differentiation, and activity of cells of
 20 these cells and tissues (e.g., lymphocytes). Examples of disorders of such cells and

tissues include various cancers (e.g., leukemias, lymphomas, and endothelial cancers such as ovarian cancers), atherosclerosis, arteriosclerosis, coronary artery disease, immune insufficiency disorders, immune hypersensitivity disorders, and congestive heart failure disorders (e.g., myocardial infarction, cardiomegaly, and cardiac valvular defects). INTERCEPT 289 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

Presence of a C-type lectin domain in INTERCEPT 289 is an indication that this protein can specifically recognize particular surfaces, such as the surface of cells of a particular type. Further supportive of this observation is the fact that human INTERCEPT 289 proteins exhibit significant sequence identity with MDL-1 which, in cooperation with DAP12 protein associated therewith, is capable of binding one or more ligands and activating one or more types of macrophages and monocytes. Aberrant activation of macrophages and monocytes is associated with a variety of immunological disorders including, for example, inflammation, asthma, hypersensitivity disorders (e.g., allergies), atopic disorders (e.g., allergic rhinitis, allergic asthma, and atopic dermatitis), anaphylaxis, urticaria (i.e., hives), autoimmune disorders (e.g., rheumatoid and juvenile arthritis, rheumatism, systemic lupus erythematosus, Grave's disease, and multiple sclerosis), graft and transplant rejection, leukemias (e.g., ALL, CML, CLL, and myelodysplastic syndrome), blood dyscrasias (e.g., multiple myeloma), polycythemia vera, myelofibrosis, leukopenias, lymphomas (e.g., Hodgkin's disease, non-Hodgkin's lymphoma, Burkitt's lymphoma, and mycosis fungoides), bacterial, viral, and parasitic infections (e.g., sepsis, influenza, common colds, hepatitis, HIV infection, malaria, and gonorrhea), immune insufficiency (e.g., AIDS), and immunodeficiency disorders. INTERCEPT 289 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

INTERCEPT 309

A cDNA clone (designated jthYa038a01t1) encoding at least a portion of human INTERCEPT 309 protein was isolated from a human thyroid tissue cDNA library. Human INTERCEPT 309 protein is an integral membrane protein having
5 three transmembrane regions and a fourth transmembrane region that can act as a signal sequence. Human INTERCEPT 309 protein is a claudin-like protein.

The full length of the cDNA encoding human INTERCEPT 309 protein (Figure 12; SEQ ID NO: 121) is 1909 nucleotide residues. The ORF of this cDNA, nucleotide residues 2 to 646 of SEQ ID NO: 121 (i.e., SEQ ID NO: 122), encodes an
10 approximately 215-amino acid residue integral membrane protein (Figure 12; SEQ ID NO: 123) having three transmembrane regions in its mature (181-amino acid residue; SEQ ID NO: 138) form.

The invention includes nucleic acid molecules which encode a polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the
15 nucleotide sequence listed in SEQ ID NO: 121, such as the portion which encodes mature INTERCEPT 309 protein, immature INTERCEPT 309 protein, or a domain of INTERCEPT 309 protein. These nucleic acids are collectively referred to as nucleic acids of the invention.

INTERCEPT 309 proteins and nucleic acid molecules encoding them
20 comprise a family of molecules having certain conserved structural and functional features.

A common domain present in INTERCEPT 309 proteins is a signal sequence. In one embodiment, a INTERCEPT 309 protein contains a signal sequence corresponding to about amino acid residues 1 to 24 of SEQ ID NO: 123 (SEQ ID
25 NO: 124). It is recognized that the carboxyl terminal boundary of the signal sequence can be located one or two residues from the residue identified above (i.e., following residues 22, 23, 24, 25, or 26 of SEQ ID NO: 123). The signal sequence is cleaved during processing of the mature protein.

INTERCEPT 309 proteins include three transmembrane domains and two pairs of extra-membrane domains that flank the cell membrane. The three transmembrane domains correspond to about amino acid residues 72 to 92, 108 to 131, and 154 to 178 of SEQ ID NO: 123 (i.e., the transmembrane domains having the sequences SEQ ID NOs: 126, 128, and 130, respectively). One pair of extra-membrane domains corresponds to about amino acid residues 25 to 71 and 132 to 153 of SEQ ID NO: 123 (these domains having the sequences SEQ ID NOs: 125 and 129). The other pair of extra-membrane domains corresponds to about amino acid residues 93 to 107 and 179 to 215 of SEQ ID NO: 123 (these domains having the sequences SEQ ID NOs: 127 and 131). In one embodiment, the first pair of extra-membrane domains (i.e., those having the sequences SEQ ID NOs: 125 and 129) are extracellular domains and the other pair of domains are cytoplasmic domains. However, in an alternative form, the first pair of extra-membrane domains are cytoplasmic and the other pair are extracellular domains.

It is recognized that, in certain forms, INTERCEPT 309 proteins can have an additional number of amino acid residues at their amino terminus. For example, the proteins can have from 1 to about 30 amino acid residues, more commonly 1 to about 12, 1 to about 10, or 1 to about 5 residues.

INTERCEPT 309 proteins typically comprise a variety of potential post-translational modification sites and protein domains (often positioned within an extracellular or protein surface domain), such as those described herein in Table VI, as predicted by computerized sequence analysis of INTERCEPT 309 proteins using amino acid sequence comparison software (comparing the amino acid sequence of INTERCEPT 309 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}).

Table VI

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 123	Amino Acid Sequence
Protein kinase C phosphorylation site	184 to 186	SYR
	191 to 193	SHR
	195 to 197	TQK
	201 to 203	TGK
Tyrosine kinase phosphorylation site	149 to 156	RELGEALY
N-myristoylation site	7 to 12	GMVGTV
	39 to 44	GLWMNC
	72 to 77	GLMCAA
	91 to 96	GMKCTR
	169 to 174	GALFCC
Amidation site	201 to 204	TGKK

In various embodiments, the protein of the invention has at least 1, 2, 4, 6, or all 11 of the post-translational modification sites and domains described herein in

5 Table VI.

Figure 12D depicts a hydrophobicity plot of an embodiment of human INTERCEPT 309 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic regions which corresponds to about amino acid residues 72 to 10 92, 108 to 131, and 154 to 178 of SEQ ID NO: 123 are the transmembrane domains of human INTERCEPT 309 described above. As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human INTERCEPT 309 protein 15 from about amino acid residue 90 to about amino acid residue 100 appears to be

located at or near the surface of the protein, while the region from about amino acid residue 70 to about amino acid residue 85 appears not to be located at or near the surface.

5 The predicted molecular weight of human INTERCEPT 309 protein without modification and prior to cleavage of the signal sequence is about 23.8 kilodaltons. The predicted molecular weight of the mature human INTERCEPT 309 protein without modification and after cleavage of the signal sequence is about 21.4 kilodaltons.

10 INTERCEPT 309 protein exhibits amino acid sequence homology with murine claudin-8 protein, as indicated in the alignment (made using the ALIGN software {Myers and Miller (1989) CABIOS, ver. 2.0}; pam120.mat scoring matrix; gap opening penalty = 12, gap extension penalty = 4) of the amino acid sequences of INTERCEPT 309 (SEQ ID NO: 123) and murine claudin-8 (SEQ ID NO: 132) proteins shown in Figure 12S. In this alignment, the two amino acid sequences are
15 about 80.0% identical. Furthermore, INTERCEPT 309 cDNA (SEQ ID NO: 121) is about 83.1% identical to the nucleotide sequence of cDNA encoding murine claudin-8 (SEQ ID NO: 133; GenBank accession no. AF087826) over the 639-residue overlapping region, as indicated in the alignment (made using the ALIGN software; pam120.mat scoring matrix; gap opening penalty = 12, gap extension penalty = 4)
20 shown in Figures 12L through 12R.

An alignment (made using the ALIGN software; pam120.mat scoring matrix; gap opening penalty = 12, gap extension penalty = 4) of the nucleotide sequences of a cDNA clone (SEQ ID NO: 134; GenBank accession no. AL049977) obtained from human fetal brain tissue and INTERCEPT 309 cDNA (SEQ ID NO: 121) is shown in
25 Figures 12E through 12K and indicates 100% sequence identity between the sequences in the overlapping portion. The overlapping portion does not overlap the INTERCEPT 309 ORF, with the exception of nucleotide residues 1 and 28-32. It is recognized that 'overlap' of the human fetal brain cDNA clone sequence with these ORF residues is an artifact of the ALIGN software, and does not represent

meaningful homology between residues 1 and 28-32 of the INTERCEPT 309 ORF and the corresponding residues of the human fetal brain cDNA clone. Nonetheless, isolation of this cDNA clone from fetal brain tissue is an indication that INTERCEPT 309 protein is expressed in fetal brain tissue.

5 An alignment (made using the LALIGN software {Huang and Miller, 1991, Adv. Appl. Math. 12:373-381}; pam120 scoring matrix, gap opening penalty = 12, gap extension penalty = 4) of the nucleotide sequence of INTERCEPT 309 cDNA (SEQ ID NO: 121) with the nucleotide sequence encoding murine latent transforming growth factor-beta binding protein-3 (LTBP-3) indicated that the two
10 sequences were 40.3% identical in a 1969-nucleotide residue overlapping portion. As disclosed in P.C.T. Publication No. WO 95/22611, latent transforming growth factor-beta binding protein 3 (LTBP-3) is a secreted protein that is expressed in murine epithelial, parenchymal, and stromal during embryonic development. LTBP-3 is thought to exhibit one or more of four activities

- 15 i) modulating intracellular biosynthesis of latent transforming growth factor-beta;
 ii) binding latent transforming growth factor-beta with extracellular matrix;
 iii) modulating activation of latent transforming growth factor-beta complexes; and
20 iv) targeting latent transforming growth factor-beta complexes to the cell surface.

 An alignment (made using the ALIGN software; pam120.mat scoring matrix, gap opening penalty = 12, gap extension penalty = 4) of the amino acid sequence of INTERCEPT 309 cDNA (SEQ ID NO: 123) with the amino acid sequence of human
25 peripheral myelin protein (PMP-22) indicated that the two protein sequences are 17.2% identical. PMP-22 is involved in myelination of peripheral nerves, particularly during development.

 Individual alignments (made using the Wisconsin™ BestFit software; Smith and Waterman (1981) Adv. Appl. Math. 2:482-489; blosum62 scoring matrix, gap

opening penalty 10 / gap extension penalty 10) of the amino acid sequence (SEQ ID NO: 123) of INTERCEPT 309 with the amino acid sequences of human (SEQ ID NO: 135; GenBank Accession No. 4502877) and murine (SEQ ID NO: 136; GenBank Accession No. BAA22985) receptors of *Clostridium perfringens* enterotoxin (CPE) and with the amino acid sequence (SEQ ID NO: 137) encoded by rat ventral prostate tissue during androgen withdrawal-induced tissue regression were manually aligned (by inserting a 'blank' at position 1 of the rRPV nucleotide sequence). The manually aligned alignments are shown in Figure 12T. The amino acid sequence of INTERCEPT 309 protein is about 43% identical to the human CPE receptor amino acid sequence, about 45% identical to the murine CPE receptor amino acid sequence, and about 43% identical to the amino acid sequence encoded by the transcript obtained from regressing rat ventral prostate tissue.

Expressed sequence tags (ESTs) which exhibit at least limited nucleotide sequence identity with SEQ ID NO: 121 have been isolated from human and murine liver, kidney, prostate, and colon tissues.

Uses of INTERCEPT 309 Nucleic acids, Polypeptides, and Modulators Thereof

INTERCEPT 309 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not expressed. Based on the observations that cDNA corresponding to INTERCEPT 309 occurs in human thyroid and fetal brain cDNA libraries, and that ESTs have been isolated from liver, kidney, prostate, and colon tissues, it is evident that INTERCEPT 309 protein is involved in one or more biological processes which occur in these tissues. In particular, INTERCEPT 309 is involved in modulating growth, proliferation, survival, differentiation, and activity (e.g., thyroid secretion activity) of cells of these tissues. Thus, INTERCEPT 309 has a role in disorders which affect the brain, thyroid, and other tissues and one or more of growth, proliferation, survival, differentiation, activity, morphology, and movement / migration of cells in

those tissues, as well as the biological function of organs (e.g., the brain, liver, colon, prostate, kidneys, and thyroid) comprising such tissues. Relevant disorders which involve these tissues are discussed separately below.

As indicated by its similarity to murine claudin-8 (e.g., as shown in Figure 12S), INTERCEPT 309 is a claudin-like protein, and can exhibit one or more of the activities exhibited by murine claudin-8 and other claudins. Claudins are proteins that are involved in formation, maintenance, and regulation of tight junctions, which are intercellular junctions that occur between cells of tissues (e.g., epithelia and endothelia) having selective permeability (Morita et al. (1999) Proc. Natl. Acad. Sci. USA 96:511-516). Tight junctions can be associated with actin fibrils, and claudins can mediate interactions between actin fibrils and other components of the tight junction. Tissues in which tight junctions occur between adjacent cells can form sheets or other structures which exhibit selective trans-tissue permeability and in which the membrane and membrane-bound components of tissue-spanning cells can be selectively localized to one side (e.g., apical or basolateral side) of the tissue. By way of example, epithelial and endothelial tissues of kidney, liver, lung, and thyroid form barriers which permit transepithelial / transendothelial passage of certain compounds and cells (e.g., secreted / excreted products and immune system cells), but not others. Tight junction alterations have also been associated with tumor differentiation, particularly in thyroid tumors (Kerjaschki et al. (1979) Am. J. Pathol. 96:207-225; Cochand-Priollet et al. (1998) Ultrastruct. Pathol. 22:413-420). INTERCEPT 309 can have a role in each of these functions, both in normal tissue and in aberrant tissue (e.g., tissue of a patient afflicted with a disorder that affects the tissue).

An important feature of tight junctions is that the permeability of a tissue comprising such intercellular junctions can be regulated by cellular and other (e.g., endocrine) processes. Thus, depending on the cellular or other influences exerted on the components of the tight junction, the permeability of the tissue to water, solutes (e.g., urea), proteins (e.g., hormones), and immune cells (e.g., T cells and

macrophages) can be regulated (Stevenson (1999) J. Clin. Invest. 104:3-4).

Regulation of transmembrane permeability is critical to the function of many organs (e.g., kidney, colon, thyroid, liver, prostate, etc.). INTERCEPT 309, being a claudin-like protein can regulate transmembrane permeability in organs and tissues in which

5 it is normally or aberrantly expressed.

One or more transmembrane proteins associated with tight junctions mediate transmembrane signal transduction which regulates, inter alia, the permeability of the junction (Fanning et al., (1999) J. Am. Soc. Nephrol. 10:1337-1345). For example, inhibition of protein tyrosine phosphorylation (a common activity associated with

10 transmembrane signaling) has been associated with aberrant thyroid epithelial cell junction formation (Yap et al., (1997) Endocrinology 138:2315-2324). INTERCEPT 309, being a transmembrane protein associated with tight junctions and having a potential tyrosine kinase phosphorylation site at residues 149-156 of SEQ ID NO: 123, can be involved in transmembrane transduction of signals between the cell

15 interior and the extracellular milieu, including signal transduction associated with regulation of tight junction function.

Claudins can also participate in cell-to-cell adhesive processes that do not necessarily involve tight junction formation. Examples of such mechanisms include binding between cells forming the blood-brain barrier, adhesion of myelin to nerve

20 fibers and to itself, and binding between skin cells to form a barrier to the passage of moisture and solutes to and from the environment. Similarity between the amino acid sequences of INTERCEPT 309 and PMP-22 is also indicative of a role of INTERCEPT 309 protein in mediating adhesion between myelin-producing cells and nerve cells (e.g., between Schwann cells and peripheral nerve cells). INTERCEPT

25 309 can therefore have a role in disorders (e.g., multiple sclerosis) involving aberrant (including insufficient) myelination or demyelination of nerve cells.

INTERCEPT 309, being a cell surface claudin-like protein, can be a substrate for interaction of pathogens (e.g., bacteria, toxins, and viruses) with host cells, and can mediate interaction of pathogens with cells which express INTERCEPT 309.

For example, Morita et al. (supra) determined that a murine claudin is a receptor for Clostridium perfringens enterotoxin (CPE). Similarity between the amino acid sequences of murine claudin-8 and INTERCEPT 309 indicates that INTERCEPT 309 can act as a receptor for CPE. Furthermore, amino acid sequence similarity
5 between INTERCEPT 309 and other human and murine CPE receptors (e.g., GenBank Accession Nos. 4502877 and BAA22985, as indicated in Figure 12T) is a further indication that INTERCEPT 309 can mediate interaction of CPE with cells upon which CPE acts. INTERCEPT 309 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to
10 prognosticate, diagnose, and treat disorders mediated by C. perfringens. Such disorders include, by way of example, gastrointestinal disorders (e.g., diarrhea, gastroenteritis, and other disorders associated with food poisoning, and certain types of pseudomembranous colitis), disorders associated with wound healing (e.g., gangrene), and other pathogenic infections (e.g., sepsis with or without intravascular
15 hemolysis). INTERCEPT 309 can, of course, also mediate interaction of other pathogens with cells which express it.

Being a claudin-like protein, INTERCEPT 309 can be involved in formation, maintenance, and regulation of structures (e.g., transmembrane protein complexes including INTERCEPT 309) that regulate the permeability of cell membranes with
20 regard to various molecules and macromolecules. Regulation of trans-tissue (i.e., intercellular) diffusion of extracellular components (e.g., water, solutes, and immune cells) and diffusion of membrane-bound and integral membrane components from one side of a tissue (e.g., the apical face of an epithelium) to the other (e.g., the basolateral face of the same epithelium; i.e., paracellular diffusion) can be modulated
25 by INTERCEPT 309 proteins and nucleic acids and by small molecules which interact with INTERCEPT 309 proteins and nucleic acids encoding them. Actin is known to be associated with tight junction components, and modifications to the actin cytoskeleton of a cell can modulate tight junction-regulated intercellular and paracellular diffusion. Thus, compositions which affect the interaction between actin

and INTERCEPT 309 protein can modulate tight junction regulation of intercellular and paracellular diffusion. In addition, agents which act directly on an INTERCEPT 309 protein or nucleic acid, without affecting the interaction between the claudin and actin, can be used to modulate tight junction regulation of intercellular and paracellular diffusion. INTERCEPT 309 protein can also act as a receptor for C. perfringens enterotoxin and for other pathogens, and INTERCEPT 309 proteins, as described herein, can be used to modulate C. perfringens enterotoxin binding and toxicity, as well as binding of other pathogens with cells and tissues which express INTERCEPT 309.

10 The fact that cDNA encoding INTERCEPT 309 was isolated from human thyroid and fetal brain cDNA libraries and the fact that INTERCEPT 309 have been isolated from liver, kidney, prostate, and colon tissues indicates that INTERCEPT 309 can have a role in disorders of these tissues, particularly including those characterized above. Examples of disorders in which INTERCEPT 309 can have a role are described in the following paragraphs a)-f), which are organized, for
15 convenience, by tissue type.

 a) Examples of brain disorders in which INTERCEPT 309 can have role include both CNS disorders, CNS-related disorders, focal brain disorders, global-diffuse cerebral disorders, and other neurological and cerebrovascular disorders.
20 CNS disorders include, but are not limited to cognitive and neurodegenerative disorders such as Alzheimer's disease, senile dementia, Huntington's disease, amyotrophic lateral sclerosis, and Parkinson's disease, as well as Gilles de la Tourette's syndrome, autonomic function disorders such as hypertension and sleep disorders (e.g., insomnia, hypersomnia, parasomnia, and sleep apnea),
25 neuropsychiatric disorders (e.g., schizophrenia, schizoaffective disorder, attention deficit disorder, dysthymic disorder, major depressive disorder, mania, and obsessive-compulsive disorder), psychoactive substance use disorders, anxiety, panic disorder, and bipolar affective disorder (e.g., severe bipolar affective disorder and bipolar affective disorder with hypomania and major depression). CNS-related

disorders include disorders associated with developmental, cognitive, and autonomic neural and neurological processes, such as pain, appetite, long term memory, and short term memory. Examples of focal brain disorders include aphasia, apraxia, agnosia, and amnesias (e.g., posttraumatic amnesia, transient global amnesia, and psychogenic amnesia). Global-diffuse cerebral disorders with which INTERCEPT 309 is associated include coma, stupor, obtundation, and disorders of the reticular formation. Cerebrovascular disorders include ischemic syndromes (e.g., stroke), hypertensive encephalopathy, hemorrhagic disorders, and disorders involving aberrant function of the blood-brain barrier (e.g., CNS infections such as meningitis and encephalitis, aseptic meningitis, metastasis of non-CNS tumor cells into the CNS, various pain disorders such as migraine, and CNS-related adverse drug reactions such as head pain, sleepiness, and confusion). INTERCEPT 309 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

b) Examples of thyroid disorders with which INTERCEPT 309 proteins and nucleic acids encoding them can be involved include hyper- and hypothyroidism, goiter, thyroiditis, thyroid cancers (e.g., adenomas and carcinomas), and autoimmune diseases involving thyroid autoantigens such as thyroglobulin and thyroperoxidase. INTERCEPT 309 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

c) Kidney disorders with which INTERCEPT 309 proteins and nucleic acids encoding them can be involved include acute and chronic renal failure, immunologically-mediated renal disorders (i.e., involving both renal antigens and extra-renal antigens that have become located within the kidneys), glomerular diseases such as acute and progressive nephritic syndromes and nephrotic syndromes, acute and chronic tubulointerstitial nephritis, infections of the kidney, nephrotoxic disorders (i.e., including those associated with antibiotics, analgesics,

anti-cancer agents, anti-epileptic agents, etc.), nephrogenic diabetes insipidus, hereditary chronic nephropathies, urinary incontinence, urinary calculus formation, kidney infections, and kidney neoplasms. INTERCEPT 309 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can
5 be used to prognosticate, diagnose, and treat one or more of these disorders.

d) Examples of liver disorders in which INTERCEPT 309 can have a role include the liver disorders described elsewhere in this disclosure.

e) Prostate disorders with which INTERCEPT 309 proteins and nucleic acids encoding them can be involved include the prostate disorders described elsewhere in
10 this disclosure.

f) Disorders of the colon in which INTERCEPT 309 can have a role include, for example, diarrhea, constipation, gastroenteritis, malabsorption syndromes such as celiac disease and tropical sprue, inflammatory bowel diseases such as Crohn's disease and ulcerative colitis, antibiotic-associated colitis, functional bowel disorders
15 such as irritable bowel syndrome and functional diarrhea, congenital anomalies (e.g., megacolon and imperforate anus), idiopathic disorders (e.g., diverticular disease such as diverticulosis and diverticulitis and melanosis coli), vascular lesions (e.g., ischemic colitis, hemorrhoids, angiodysplasia), inflammatory diseases (e.g., idiopathic ulcerative colitis, pseudomembranous colitis, and lymphopathia
20 venereum), and colon tumors (e.g., hyperplastic polyps, adenomatous polyps, bronchogenic cancer, colonic carcinoma, squamous cell carcinoma, adenoacanthomas, sarcomas, lymphomas, argentaffinomas, carcinoids, and melanocarcinomas). INTERCEPT 309 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to
25 prognosticate, diagnose, and treat one or more of these disorders.

INTERCEPT 309 (like claudins) regulates intercellular permeability in tissues through which one may wish to modulate the passage of drugs or other agents. Such tissues include, for example, the blood-brain barrier (e.g., at the choroid plexus), vascular endothelium, and liver epithelial tissues (i.e., other than

fenestrated hepatic vascular epithelia). By way of example, one may wish either to enhance the permeability of a tissue with respect to a drug (e.g., a drug for which enhanced blood-brain barrier permeability is desired) or to reduce the permeability of a tissue with respect to a drug (e.g., a drug for which reduction of hepatic sequestration is desired). INTERCEPT 309 proteins and nucleic acids, and other compounds which modulate the structure or activity of INTERCEPT 309 proteins and nucleic acids, can be used to regulate the permeability of such tissues.

In addition to its structural and functional similarity with claudin proteins, INTERCEPT 309 protein is also similar in sequence to at least one protein regulator of apoptosis. As shown in Figure 12T, the amino acid sequence of INTERCEPT 309 is similar to the amino acid sequence of a protein (rRPV) which is expressed specifically in regressing rat ventral prostate tissue and epididymis. As described by Briehl et al. (1991, Mol. Endocrinol. 5:1381-1388), expression of this rat protein is elevated 3- to 8-fold in ventral prostate tissue upon induction of tissue regression mediated by withdrawal of androgens. Androgen withdrawal induces apoptosis in rat ventral prostate tissue. Thus, the rat protein described by Briehl et al. (supra) is an apoptosis-associated protein. INTERCEPT 309, having a sequence similar to that of rRPV, can also modulate apoptosis in tissues in which it is expressed.

Apoptosis is a process of controlled cell death that occurs normally in many tissues in which cell division occurs essentially continuously. Examples of such tissues include nearly all tissues other than adult brain and cardiac muscle tissues, and particularly include rapidly-growing and rapidly-replaced tissues such as epithelial and endothelial tissues. Elimination of abnormal or damaged cells from a tissue (other than adult brain or cardiac muscle tissues) frequently occurs by apoptosis of the abnormal or damaged cells, rather than by necrosis, which can lead to inflammation. Apoptosis thus represents an important homeostatic process in healthy individuals, and aberrance in normal apoptosis can lead to occurrence of one or more disorders. INTERCEPT 309 (which, as described above is similar to the rat protein of Briehl et al.) can also be associated with apoptosis. INTERCEPT 309 can

modulate apoptosis in tissues in which it is expressed, both under normal (i.e., homeostatic, non-disorder-associated) conditions and in tissue affected by a disorder associated with aberrant apoptosis. Disorders associated with aberrant apoptosis include both disorders in which apoptosis occurs to a supra-normal degree (e.g.,

5 human immunodeficiency virus-mediated depletion of CD4+ T cells) and disorders in which apoptosis is inhibited, relative to normal levels (e.g., various cancers and viral infections characterized by survival of virus-infected cells). Examples of disorders associated with aberrant apoptosis include substantially all cancers and viral infections, obesity, diabetes, atherosclerosis, arteriosclerosis, coronary artery

10 disease, and angiogenesis. INTERCEPT 309 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

MANGO 419

15 A cDNA clone (designated cohqf013f05) encoding at least a portion of human MANGO 419 protein was isolated from a human cDNA library prepared from prostate carcinoma tissue which had metastasized to liver. Human MANGO 419 protein is a secreted protein.

The full length of the cDNA encoding human MANGO 419 protein (Figure

20 13; SEQ ID NO: 141) is 323 nucleotide residues. The ORF of this cDNA, nucleotide residues 84 to 323 of SEQ ID NO: 141 (i.e., SEQ ID NO: 142), encodes an 80-amino acid residue (or longer) protein (Figure 13; SEQ ID NO: 143), corresponding to a 56-residue (or longer) secreted mature protein.

The invention thus includes purified human MANGO 419 protein, both in the

25 form of the immature 80 amino acid residue protein (SEQ ID NO: 143) and in the form of the mature 56 amino acid residue protein (SEQ ID NO: 145). Mature human MANGO 419 proteins can be synthesized without the signal sequence polypeptide at the amino terminus thereof, or they can be synthesized by generating immature MANGO 419 protein and cleaving the signal sequence therefrom.

MANGO 419 protein can have one or more amino acid residues attached at the carboxyl terminal end thereof. By way of example, there can be from 1 to about 500, 1 to 100, 1 to 50, 1 to 30, 1 to 20, or 1 to 10 additional amino acid residues.

5 The invention includes nucleic acid molecules which encode a polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the nucleotide sequence listed in SEQ ID NO: 141, such as the portion which encodes mature MANGO 419 protein, immature MANGO 419 protein, or a domain of MANGO 419 protein. These nucleic acids are collectively referred to as nucleic acids of the invention.

10 MANGO 419 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional features.

A common domain present in MANGO 419 proteins is a signal sequence. In one embodiment, a MANGO 419 protein contains a signal sequence corresponding to the portion of the protein from amino acid residue 1 to about amino acid residue 15 24 of SEQ ID NO: 143 (SEQ ID NO: 144). It is recognized that the carboxyl terminal boundary of the signal sequence can be located one or two residues from the residue identified above (i.e., following residues 22, 23, 24, 25, or 26 of SEQ ID NO: 143). The signal sequence is cleaved during processing of the mature protein.

20 MANGO 419 proteins typically comprise a variety of potential post-translational modification sites and protein domains (often positioned within an extracellular or protein surface domain), such as those described herein in Table VII, as predicted by computerized sequence analysis of MANGO 419 proteins using amino acid sequence comparison software (comparing the amino acid sequence of MANGO 419 with the information in the PROSITE database {rel. 12.2; Feb, 1995} 25 and the Hidden Markov Models database {Rel. PFAM 3.3}).

Table VII

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 143	Amino Acid Sequence
Casein kinase II phosphorylation site	31 to 34	TFGE
	55 to 58	SSDD
N-myristoylation site	43 to 48	GCRGCC

In various embodiments, the protein of the invention has at least 1, 2, or all 3 of the post-translational modification sites and domains described herein in Table

5 VII.

The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that human MANGO 419 protein includes an approximately 24 amino acid residue signal peptide (amino acid residues 1 to about 24 of SEQ ID NO: 143; SEQ ID NO: 144) preceding the mature MANGO 419
10 protein (amino acid residues 25 to 80 of SEQ ID NO: 143; SEQ ID NO: 145).

Figure 13B depicts a hydrophobicity plot of human MANGO 419 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to about 24 of SEQ ID NO: 143 is the
15 signal sequence of human MANGO 419 (SEQ ID NO: 144). As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human MANGO 419 protein from about amino acid residue 35 to about amino acid residue 55 appears to be located at
20 or near the surface of the protein, while the region from about amino acid residue 60 to about amino acid residue 65 appears not to be located at or near the surface.

The predicted molecular weight of human MANGO 419 protein without modification and prior to cleavage of the signal sequence is about 8.8 kilodaltons.

The predicted molecular weight of the mature human MANGO 419 protein without modification and after cleavage of the signal sequence is about 6.2 kilodaltons.

Expressed sequence tags (ESTs) which exhibit homology with SEQ ID NO: 141 have been isolated from murine mammary and embryonic tissues. Those ESTs have sequences that are similar to the sequence of a nucleic acid encoding an inner ear-specific collagen precursor.

Uses of MANGO 419 Nucleic acids, Polypeptides, and Modulators Thereof

MANGO 419 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not expressed. Based on the observations that cDNA corresponding to MANGO 419 occurs in a human metastatic prostate carcinoma cDNA library, and that ESTs obtained from mammary and embryonic tissues exhibit homology with MANGO 419 cDNA, it is evident that MANGO 419 protein can be involved in one or more biological processes which occur in these tissues. In particular, MANGO 419 can be involved in modulating growth, proliferation, survival, differentiation, and activity of cells of these tissues (e.g., mammary, prostate, and other epithelial and endothelial cells). MANGO 419 can have a role in disorders which affect epithelial and endothelial tissues including, for example, prostate, breast, and embryonic tissues. MANGO 419 proteins, nucleic acids encoding them, and small molecules which interact with either of these can be used to prognosticate, diagnose, and treat disorders of epithelial and endothelial tissues, particularly including carcinogenesis and metastasis of epithelial and endothelial neoplasms, such as prostate and mammary cancers.

Recovery of a cDNA encoding MANGO 419 from a library prepared using metastatic prostate carcinoma cells also indicates that MANGO 419 can affect the ability and propensity of a cell to adhere with other cells or with extracellular surfaces, and that MANGO 419 can affect the ability of cells which express it to

move through other tissues and through extracellular matrix. Furthermore, the fact that MANGO 419 is a secreted protein indicates that it can be used (e.g., by detecting it in a body fluid) as a marker for the metastatic state of cancers, particularly including epithelial carcinomas.

5 Expression of MANGO 419 protein in epithelial tissues such as prostate and mammary tissues is an indication that MANGO 419 protein and nucleic acids which encode them can be involved in disorders of epithelial and endothelial tissues. Examples of disorders of epithelial and endothelial tissues include cell binding, adhesion, and proliferation disorders and epithelial / endothelial permeability-related
10 disorders. MANGO 419 protein is involved in disorders associated with aberrant binding or adhesion of cells with other cells, with extracellular matrix, or with foreign materials. Disorders involving aberrant binding or adhesion of cells with other cells include both disorders in which cells normally bind with one another (e.g., metastasis of a cancerous cells away from a solid tissue site at which they
15 normally occur or immune hypersensitivity) and disorders in which the cells do not normally bind with one another, but do bind with one another in individuals afflicted with the disorder (e.g., autoimmune disorders, infections, wherein cells with which T cells bind are not normally present in the animal, or disorders associated with abnormal blood coagulation). Disorders involving aberrant binding or adhesion of
20 cells with extracellular matrix include those (e.g., metastasis of a normally solid tumor tissue away from it site of origin) in which the cells normally do, but aberrantly do not, bind with extracellular matrix as well as those (e.g., metastasis of tumor cells into a tissue in which the cells do not normally occur, autoimmune disorders, liver fibrosis, abnormal blood coagulation, atherosclerosis, and
25 arteriosclerosis) in which the cells normally do not bind with extracellular matrix, but aberrantly do. Examples of disorders involving aberrant binding or adhesion of cells with foreign materials include those (e.g., allergies and hypersensitivity disorders such as latex hypersensitivity) associated with aberrant binding with the foreign material and disorders in which the cells normally bind with the foreign

material, but aberrantly do not. MANGO 419 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

Expression of MANGO 419 protein in epithelial tissues such as prostate and
5 mammary tissues is an indication that MANGO 419 proteins and nucleic acids can be involved in disorders associated with aberrant permeability of epithelial tissues (i.e., aberrant permeability with regard to water, solutes, proteins, immune cells, and pathogens). Such disorders include, by way of example, kidney disorders, liver disorders, gastrointestinal disorders, endocrine and exocrine disorders, prostate
10 disorders, gynecological disorders, skin disorders, and brain disorders. Examples of disorders of these types are described separately, for convenience, in the following paragraphs a)-h).

a) Kidney disorders with which MANGO 419 proteins and nucleic acids encoding them can be involved include the kidney disorders described elsewhere in
15 this disclosure. MANGO 419 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

b) Examples of liver disorders in which MANGO 419 can have a role include the liver disorders described elsewhere in this disclosure. MANGO 419 proteins,
20 nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

c) Disorders of the gastrointestinal tract in which MANGO 419 can have a role include, for example, gastroesophageal reflux disease, gastric ulcers, gastritis,
25 appendicitis, peritonitis, diarrhea, constipation, gastroenteritis, malabsorption syndromes such as celiac disease and tropical sprue, inflammatory bowel diseases such as Crohn's disease and ulcerative colitis, antibiotic-associated colitis, functional bowel disorders such as irritable bowel syndrome and functional diarrhea, diverticular diseases such as diverticulosis and diverticulitis, and benign and

malignant neoplasms of the colon. MANGO 419 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

d) Examples of endocrine and exocrine disorders with which MANGO 419 proteins and nucleic acids encoding them can be involved include diabetes mellitus, hypoglycemia, glucagon disorders, pituitary disorders such as diabetes insipidus, thyroid disorders such as hyper- and hypothyroidism, adrenal disorders such as Cushing's syndrome and hyperaldosteronism, multiple endocrine neoplasias, polyglandular deficiency syndromes, epithelial breast cancers, biliary calculi, cholecystitis, and neoplasms of the bile ducts, chronic and acute renal failure, immunologically mediated renal diseases, glomerular diseases such as acute nephritic syndrome and nephrotic syndrome, tubulointerstitial diseases, nephrotoxic disorders, and infections of the kidney, goiter, thyroiditis, thyroid cancers, and autoimmune diseases involving endocrine (e.g., thyroid) autoantigens. MANGO 419 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

e) Prostate disorders with which MANGO 419 proteins and nucleic acids encoding them can be involved include prostate neoplasms, benign prostatic hyperplasia, and benign prostatic hypertrophy. MANGO 419 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

f) Gynecological disorders in which MANGO 419 can have a role include ovarian, cervical, vulvar, and vaginal cancers, infertility, and endometriosis. MANGO 419 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

g) Skin disorders with which MANGO 419 can be associated include psoriasis, infections, wounds (and healing of wounds), inflammation, dermatitis,

acne, and benign and malignant dermatological tumors. MANGO 419 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

- 5 h) Examples of brain disorders in which MANGO 419 can have a role include the brain disorders described elsewhere in this disclosure. MANGO 419 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

10

INTERCEPT 429

A cDNA clone (designated jchrd012h06) encoding at least a portion of human INTERCEPT 429 protein was isolated from a human heart cDNA library. Human INTERCEPT 429 protein is a transmembrane protein.

- 15 The full length of the cDNA encoding human INTERCEPT 429 protein (Figure 14; SEQ ID NO: 151) is 546 nucleotide residues. The ORF of this cDNA, nucleotide residues 95 to 439 of SEQ ID NO: 151 (i.e., SEQ ID NO: 152), encodes a 115-amino acid residue protein (Figure 14; SEQ ID NO: 153), corresponding to a 93-residue transmembrane mature protein.

- 20 The invention includes purified human INTERCEPT 429 protein, both in the form of the immature 115 amino acid residue protein (SEQ ID NO: 153) and in the form of the mature 93 amino acid residue protein (SEQ ID NO: 155). Mature human INTERCEPT 429 proteins can be synthesized without the signal sequence polypeptide at the amino terminus thereof, or they can be synthesized by generating
25 immature INTERCEPT 429 protein and cleaving the signal sequence therefrom.

The invention includes nucleic acid molecules which encode a polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the nucleotide sequence listed in SEQ ID NO: 151, such as the portion which encodes mature INTERCEPT 429 protein, immature INTERCEPT 429 protein, or a domain

of INTERCEPT 429 protein. These nucleic acids are collectively referred to as nucleic acids of the invention.

INTERCEPT 429 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional
5 features.

A common domain present in INTERCEPT 429 proteins is a signal sequence. In one embodiment, an INTERCEPT 429 protein contains a signal sequence corresponding to the portion of the protein from amino acid residue 1 to about amino acid residue 22 of SEQ ID NO: 153 (SEQ ID NO: 154). It is recognized that the
10 carboxyl terminal boundary of the signal sequence can be located one or two residues from the residue identified above (i.e., following residues 20, 21, 22, 23, or 24 of SEQ ID NO: 153). The signal sequence is cleaved during processing of the mature protein.

INTERCEPT 429 proteins include two transmembrane domains, a pair of
15 extra-membrane domains that flank the cell membrane on the same side of the membrane, and another extra-membrane domain that flanks the cell membrane on the opposite side of the membrane. The two transmembrane domains correspond to about amino acid residues 32 to 49 and 59 to 82 of SEQ ID NO: 153 (i.e., the transmembrane domains having the sequences SEQ ID NOs: 157 and 159). The pair
20 of extra-membrane domains corresponds to about amino acid residues 23 to 31 and 83 to 115 of SEQ ID NO: 153 (these domains having the sequences SEQ ID NOs: 156 and 160). The other extra-membrane domain corresponds to about amino acid residues 50 to 58 of SEQ ID NO: 153 (this domain having the sequence SEQ ID NO: 158). In one embodiment, the pair of extra-membrane domains (i.e., those having
25 the sequences SEQ ID NOs: 156 and 160) are intracellular domains and the other domain is an extracellular domain. However, in an alternative form, the pair of extra-membrane domains are extracellular and the other domain is cytoplasmic.

INTERCEPT 429 proteins typically comprise a variety of potential post-translational modification sites and protein domains (often positioned within an

extracellular or protein surface domain), such as those described herein in Table VIII, as predicted by computerized sequence analysis of INTERCEPT 429 proteins using amino acid sequence comparison software (comparing the amino acid sequence of INTERCEPT 429 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}).

Table VIII

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 153	Amino Acid Sequence
N-glycosylation site	88 to 91	NRSA
Casein kinase II phosphorylation site	93 to 96	TKCD

In various embodiments, the protein of the invention has one or both of the post-translational modification sites and domains described herein in Table VIII.

Figure 14B depicts a hydrophobicity plot of human INTERCEPT 429 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to 22 of SEQ ID NO: 153 is the signal sequence of human INTERCEPT 429 (SEQ ID NO: 154). As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human INTERCEPT 429 protein from about amino acid residue 85 to about amino acid residue 100 appears to be located at or near the surface of the protein.

The predicted molecular weight of human INTERCEPT 429 protein without modification and prior to cleavage of the signal sequence is about 13.4 kilodaltons. The predicted molecular weight of the mature human INTERCEPT 429 protein without modification and after cleavage of the signal sequence is about 10.8 kilodaltons.

Expressed sequence tags (ESTs) which exhibit homology with SEQ ID NO: 151 have been isolated from murine small intestine tissue and from pooled human fetal lung, testis, and B cell tissues.

5 Uses of INTERCEPT 429 Nucleic acids,
 Polypeptides, and Modulators Thereof

INTERCEPT 429 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not expressed. Based on the observations that cDNA corresponding to INTERCEPT 429
10 occurs in a human heart cDNA library, and that ESTs obtained from small intestine and one or more of fetal lung, testis, and B cell tissues exhibit homology with MANGO 419 cDNA, it is evident that INTERCEPT 429 protein can be involved in one or more biological processes which occur in these tissues. In particular, INTERCEPT 429 is involved in modulating growth, proliferation, survival,
15 differentiation, and activity of cells of these tissues (e.g., cardiac muscle cells), both in normal (i.e., non-diseased) tissues and in tissues which are affected by one or more disorders. Examples of disorders with which INTERCEPT 429 protein can be associated are described in the following paragraphs.

Heart disorders with one or more of which INTERCEPT 429 proteins and
20 nucleic acids can be involved include the cardiovascular disorders described elsewhere in this disclosure. INTERCEPT 429 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

Muscular disorders in which INTERCEPT 429 proteins and nucleic acids can
25 have a role include muscular dystrophies, myotonic myopathies, glycogen storage disorders and familial periodic paralysis. INTERCEPT 429 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

Lung disorders with which INTERCEPT 429 proteins and nucleic acids can be associated include, by way of example, asthma, chronic and acute bronchitis, chronic airway obstructive disorders, pulmonary embolism, pneumonia, and genesis and metastasis of lung tumors. INTERCEPT 429 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

Testicular disorders which can involve INTERCEPT 429 proteins and nucleic acids include, for example, epididymo-orchitis, mumps orchitis, and genesis and metastasis of testicular cancers. INTERCEPT 429 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

B cell disorders in which INTERCEPT 429 proteins and nucleic acids can be involved include leukemias, lymphomas, leukopenias, plasma cell dyscrasias, and splenomegaly. INTERCEPT 429 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, and treat one or more of these disorders.

TANGO 210

A cDNA clone (designated jthke034a06) encoding at least a portion of human TANGO 210 protein was isolated from a human fetal skin cDNA library. A corresponding murine cDNA clone (designated jtmMa065g07) was isolated from a long term bone marrow cDNA library. The 'long term' bone marrow cDNA library was made by reverse transcription of mRNA obtained from bone marrow cells which were cultured for a period (generally two weeks) prior to stimulating the cells using yeast hyphae and thereafter obtaining mRNA from the cells. Human TANGO 210 protein is predicted by structural analysis to be a secreted protein although, in an alternative form, human TANGO 210 protein has a transmembrane region located near its carboxyl terminal end. Murine TANGO 210 protein is a secreted protein.

The full length of the cDNA encoding human TANGO 210 protein (Figure 15; SEQ ID NO: 171) is 1684 nucleotide residues. The open reading frame (ORF) of this cDNA, nucleotide residues 45 to 1583 of SEQ ID NO: 171 (i.e., SEQ ID NO: 172), encodes a 513-amino acid residue protein (Figure 15; SEQ ID NO: 173), corresponding to a 496-residue secreted protein.

The invention thus includes purified human TANGO 210 protein, both in the form of the immature 513 amino acid residue protein (SEQ ID NO: 173) and in the form of the mature 496 amino acid residue protein (SEQ ID NO: 175). Mature human TANGO 210 protein can be in its secreted or membrane-bound form, as described below. The invention also includes purified murine TANGO 210 protein, both in the form of the immature 511-amino acid residue protein (SEQ ID NO: 183) and in the form of the mature 494-amino acid residue protein (SEQ ID NO: 185). Mature human or murine TANGO 210 proteins can be synthesized without the signal sequence polypeptide at the amino terminus thereof, or they can be synthesized by generating immature TANGO 210 protein and cleaving the signal sequence therefrom.

The invention includes nucleic acid molecules which encode a polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the nucleotide sequence listed in SEQ ID NO: 171 or some portion thereof or SEQ ID NO: 181 or some portion thereof, such as the portion which encodes mature human or murine TANGO 210 protein, immature human or murine TANGO 210 protein, or a domain of human or murine TANGO 210 protein. These nucleic acids are collectively referred to as nucleic acids of the invention.

TANGO 210 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional features.

A common domain present in TANGO 210 proteins is a signal sequence. In one embodiment, a TANGO 210 protein contains a signal sequence corresponding to the portion of the protein from amino acid residue 1 to about amino acid residue 17 of SEQ ID NO: 173 (SEQ ID NO: 174) or to the portion of the protein from amino acid residue 1 to about amino acid residue 17 of SEQ ID NO: 183 (SEQ ID NO: 184). It is

recognized that the carboxyl terminal boundary of the signal sequence can be located one or two residues from the residue identified above (i.e., at residue 15, 16, 17, 18, or 19 of SEQ ID NO: 173 or at residue 15, 16, 17, 18, or 19 of SEQ ID NO: 183). The signal sequence is cleaved during processing of the mature protein.

5 TANGO 210 proteins can also include an extracellular domain. Murine TANGO 210 protein is secreted. However, in one alternative form, the human TANGO 210 protein is a transmembrane protein having an extracellular domain located from about amino acid residue 25 to amino acid residue 488 of SEQ ID NO: 173 (i.e., SEQ ID NO: 178). In this alternative form, human TANGO 210 protein also
10 has a transmembrane region (i.e., about amino acid residues 489 to 506 of SEQ ID NO: 173; SEQ ID NO: 179) and an intracellular domain (i.e., about amino acid residues 507 to 513 of SEQ ID NO: 173; SEQ ID NO: 180). In another alternative form, human TANGO 210 protein has an intracellular domain located from about amino acid residue 25 to amino acid residue 488 of SEQ ID NO: 173 (i.e., SEQ ID NO: 178), a
15 transmembrane region (i.e., about amino acid residues 489 to 506 of SEQ ID NO: 173; SEQ ID NO: 179), and an extracellular domain (i.e., about amino acid residues 507 to 513 of SEQ ID NO: 173; SEQ ID NO: 180).

TANGO 210 proteins typically comprise a variety of potential post-translational modification sites (often within an extracellular domain), domains, or
20 both, such as those described herein in Tables IX (for human TANGO 210) and X (for murine TANGO 210), as predicted by computerized sequence analysis of TANGO 210 proteins using amino acid sequence comparison software (comparing the amino acid sequence of TANGO 210 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}).

In various embodiments, the protein of the invention has at least 1, 2, 4, 6, 10, 15, or 20 or more of the post-translational modification sites described herein in Tables IX and X.

Examples of additional domains present in human and murine TANGO 210 protein include hemopexin domains and peptidase_M10 domains and signature sequences corresponding to hemopexin domains, zinc-binding domains, and matrix metalloproteinase (MMP) cysteine switches. In one embodiment, the protein of the invention has at least one domain or signature sequence that is at least 55%, preferably at least about 65%, more preferably at least about 75%, yet more preferably at least about 85%, and most preferably at least about 95% identical to one of the domains and signature sequences described herein in Tables IX and X. Preferably, the protein of the

invention has at least one hemopexin domain, one peptidase_M10 domain, one hemopexin domain signature sequence, one zinc-binding domain signature sequence, and one MMP cysteine switch signature sequence.

Hemopexin domains derive their name from a portion of a protein designated hemopexin. Hemopexin is a serum glycoprotein that binds with heme and transports it to the liver. Hemopexin domains facilitate binding of the protein comprising the domain with a variety of molecules and other proteins. Besides hemopexin, hemopexin domains occur in MMPs and in vitronectin, a cell adhesion and factor (Hunt et al. (1987) Prot. Seq. Data Anal. 1:21-26; Stanley (1986) FEBS Lett. 199:249-253. A consensus hemopexin domain signature sequence has been identified (Pfam Accession PDOC00023), which has the structure

(L, I, A, or T)-X₃-W-X_(2 or 3)-(P or E)-X₂-(L, I, V, M, F, or Y)-(D, E, N, Q, or S)-(S, T, or A)-(A or V)-(L, I, V, M, F, or Y), (SEQ ID NO: 451) wherein standard single-letter amino acid codes are used, X being any amino acid residue. Each of the human and murine TANGO 210 amino acid sequences include a single copy of this consensus sequence. This consensus sequence occurs in the amino acid sequences of many MMPs, including MMPs-1, -2, -3, -9, -10, -11, -12, -14, -15, and -16.

Peptidase_M10 domains are conserved amino acid sequences which occur in type 10 zinc-dependent metalloproteinases, according to the classification of Rawlings et al. (1995, Meth. Enzymol 248:183-228). Several mammalian MMPs are type 10 zinc-dependent metalloproteinases including, for example, MMP-1 (interstitial collagenase), MMP-2 (72 kilodalton gelatinase), MMP-3 (stromelysin-1) MMP-7 (matrylisin), MMP-8 (neutrophil collagenase), MMP-9 (92 kilodalton gelatinase), and MMP-10 (stromelysin-2; Woessner, 1991, FASEB J. 5:2145-2154). The peptidase_M10 domain includes a consensus zinc-binding domain signature sequence having the structure

(G, S, T, A, L, I, V, or N)-X₂-H-E-(L, I, V, M, F, Y, or W)-(D, E, G, H, R, K, or P)-H-X-(L, I, V, M, F, Y, W, G, S, P, or Q), (SEQ ID NO: 452)

wherein standard single-letter amino acid codes are used, X being any amino acid residue. The two histidine residues of the consensus sequence have been recognized as zinc ligands, and the glutamate residue is the (proteinase) active site residue. Each of the human and murine TANGO 210 amino acid sequences include this consensus
5 sequence.

Another distinguishing characteristic of mammalian extracellular MMPs is presence in the amino acid sequence of the MMP of an MMP cysteine switch signature. The consensus MMP cysteine switch signature sequence has the structure

P-R-C-(G or N)-X-P-(D or R)-(L, I, V, S, A, P, K, or Q) (SEQ ID NO: 453)

10 wherein standard single-letter amino acid codes are used, X being any amino acid residue. Each of the human and murine TANGO 210 amino acid sequences include a single copy of this consensus sequence. Human MMPs in which this consensus sequence occurs include MMPs-1, -2, -3, -7, -8, -9, -10, -11, -12, -13, -14, -15, and -16.

The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein
15 Engineering 10:1-6) predicted that human TANGO 210 protein includes an approximately 17 amino acid signal peptide (amino acid residues 1 to 15, 16, 17, 18, or 19 of SEQ ID NO: 173; SEQ ID NO: 174) preceding the mature, secreted TANGO 210 protein (amino acid residues 18 to 513 of SEQ ID NO: 173; SEQ ID NO: 175). In one alternative form, human TANGO 210 protein includes an extracellular domain (amino
20 acid residues 18 to 488 of SEQ ID NO: 173; SEQ ID NO: 178), a transmembrane domain (amino acid residues 489 to 506 of SEQ ID NO: 173; SEQ ID NO: 179), and a cytoplasmic domain (amino acid residues 507 to 513 of SEQ ID NO: 173; SEQ ID NO: 180). In another alternative form, human TANGO 210 protein includes a cytoplasmic domain (amino acid residues 18 to 488 of SEQ ID NO: 173; SEQ ID NO: 178), a
25 transmembrane domain (amino acid residues 489 to 506 of SEQ ID NO: 173; SEQ ID NO: 179), and an extracellular domain (amino acid residues 507 to 513 of SEQ ID NO: 173; SEQ ID NO: 180).

Figure 15E depicts a hydrophobicity plot of human TANGO 210 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively

hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to about 17 of SEQ ID NO: 173 is the signal sequence of human TANGO 210 (SEQ ID NO: 174). The hydrophobic region which corresponds to amino acid residues 489 to 506 of SEQ ID NO: 173 is the

5 transmembrane portion in the alternative form of human TANGO 210 protein. As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human TANGO 210 protein from about amino acid residue 190 to about amino acid residue 205

10 appears to be located at or near the surface of the protein, while the region from about amino acid residue 145 to about amino acid residue 155 appears not to be located at or near the surface.

The predicted molecular weight of human TANGO 210 protein without modification and prior to cleavage of the signal sequence is about 59.0 kilodaltons.

15 The predicted molecular weight of the mature human TANGO 210 protein without modification and after cleavage of the signal sequence is about 57.0 kilodaltons.

Northern hybridization experiments using human tissue samples indicated that mRNA corresponding to the cDNA encoding TANGO 210 is expressed in the tissues listed in Table XI, wherein "+" indicates detectable expression and "-" indicates failure

20 to detect expression.

Table XI

Animal	Tissue	Expression
Human (Adult)	kidney	+
	heart	-
	brain	-
	placenta	-
	lung	-
	liver	-
	skeletal muscle	-
	pancreas	-
Human (Fetus)	kidney	+

Human TANGO 210 exhibits sequence similarity to human MMP-8 (GENBANK™ Accession No. J05556), as indicated herein in Figures 15V and 15W, which list an alignment of the amino acid sequences of these proteins. Figures 15X-1 through 15X-6 depict an alignment of the nucleotide sequences of the ORFs of human TANGO 210 (SEQ ID NO: 172) and MMP-8 (SEQ ID NO: 176). In these alignments (each made using the ALIGN software; pam120.mat scoring matrix; gap penalties -12/-4), the amino acid and ORF nucleotide sequences corresponding to these two proteins are 43.9% identical and 57.1% identical, respectively.

The full length of the cDNA encoding murine TANGO 210 protein (Figure 15; SEQ ID NO: 181) is 2467 nucleotide residues. The ORF of this cDNA, nucleotide residues 22 to 927 and about 1280 to 1906 of SEQ ID NO: 181 (i.e., collectively, SEQ ID NO: 182), encodes a 510-amino acid residue protein (Figure 15; SEQ ID NO: 183). It is recognized that the precise locations of the intron boundaries in SEQ ID NO: 181 have not been identified. Thus, murine TANGO 210 protein can comprise one or more

additional or one or more fewer amino acid residues at the exon-exon boundary (i.e., between about residues 302 and 303 of SEQ ID NO: 183).

The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that murine TANGO 210 protein includes an
5 approximately 17 amino acid signal peptide (amino acid residues 1 to about 17 of SEQ ID NO: 183; SEQ ID NO: 184) preceding the mature TANGO 210 protein (amino acid residues 18 to 511 of SEQ ID NO: 183; SEQ ID NO: 185). Murine TANGO 210 protein is a secreted protein.

Figure 15J depicts a hydrophobicity plot of murine TANGO 210 protein.
10 Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to about 17 of SEQ ID NO: 183 is the signal sequence of murine TANGO 210 (SEQ ID NO: 184). As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a
15 protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of murine TANGO 210 protein from about amino acid residue 18 to about amino acid residue 28 appears to be located at or near the surface of the protein, while the region from about amino acid residue 148 to about amino acid residue 158 appears not to be located at or near the surface

20 The predicted molecular weight of murine TANGO 210 protein without modification and prior to cleavage of the signal sequence is about 58.7 kilodaltons. The predicted molecular weight of the mature murine TANGO 210 protein without modification and after cleavage of the signal sequence is about 56.2 kilodaltons.

Human and murine TANGO 210 proteins exhibit considerable sequence
25 similarity, as indicated herein in Figures 15K and 15L. Figures 15K and 15L depict an alignment of human and murine TANGO 210 amino acid sequences (SEQ ID NOs: 173 and 183, respectively). In this alignment (made using the ALIGN software {Myers and Miller (1989) CABIOS, ver. 2.0}; pam120.mat scoring matrix; gap penalties -12/-4), the proteins are 77.2% identical in the overlapping region (i.e., 393

identical residues out of 509 residues in the overlapping region, which includes amino acid residues 1-509 of SEQ ID NO: 173 and amino acid residues 1-509 of SEQ ID NO: 183). The human and murine cDNAs encoding TANGO 210 are 76.2% identical in the overlapping portions (i.e., nucleotide residues 29-1601 of SEQ ID NO: 171 and
5 nucleotide residues 8-927 and 1280-1935 of SEQ ID NO: 181), as assessed using the same software and parameters and as indicated in Figures 15M through 15U. In the respective ORFs, SEQ ID NOs: 171 and 181 are 81.7% identical.

Human TANGO 210 Gene Expression Analysis

10 Expression of TANGO 210 in selected human tissues and cell types was analyzed as follows. Total RNA was prepared from selected human tissues using a single step extraction method using the RNA STAT-60™ kit according to the manufacturer's instructions (TelTest, Inc). Each RNA preparation was treated with DNase I (Ambion) at 37°C for 1 hour. DNase I treatment was considered to be
15 complete if the sample required at least 38 PCR amplification cycles to reach a threshold level of fluorescence using β -2 microglobulin as an internal amplicon reference. The integrity of the RNA samples following DNase I treatment was confirmed by agarose gel electrophoresis and ethidium bromide staining. Following phenol extraction, cDNA was prepared from the sample using the SUPERSCRIPT™
20 Choice System following the manufacturer's instructions (Gibco BRL). A negative control of RNA without reverse transcriptase was mock reverse-transcribed for each RNA sample.

TANGO 210 expression was measured by TAQMAN® quantitative PCR (Perkin Elmer Applied Biosystems) in cDNA prepared from the following normal
25 human tissues: prostate, liver, breast, skeletal muscle, brain, colon, heart, ovary, kidney, lung, vein, aorta, testis, thyroid, placenta, fetal liver, fetal heart, osteoblasts (undifferentiated), small intestine, spleen, thymus, and lymph node. Probes were designed by PRIMEREXPRESS™ software (PE Biosystems) based on the sequence of each gene.

Each gene probe was labeled using FAM (6-carboxyfluorescein), and the β 2-microglobulin reference probe was labeled with a different fluorescent dye, VIC. The differential labeling of the target gene and internal reference gene thus enabled measurement in same well. Forward and reverse primers and the probes for both β 2-microglobulin and target gene were added to the TAQMAN® Universal PCR Master Mix (PE Applied Biosystems). Although the final concentration of primer and probe varied, each was internally consistent within a given experiment. A typical experiment contained 200 nanomolar forward and reverse primers and 100 nanomolar probe for β -2 microglobulin, and 600 nanomolar forward and reverse primers and 200 nanomolar probe for the target gene. TAQMAN® matrix experiments were carried out using an ABI PRISM™ 7700 Sequence Detection System (PE Applied Biosystems). The thermal cycler conditions were as follows: hold for 2 minutes at 50°C and 10 minutes at 95°C, followed by two-step PCR for 40 cycles of 95°C for 15 seconds followed by 60°C for 1 minute.

The following method was used to quantitatively calculate TANGO 210 gene expression in the selected tissues relative to β -2 microglobulin expression in the same tissue. The threshold cycle (Ct) value is defined as the cycle at which a statistically significant increase in fluorescence is detected. A lower Ct value is indicative of a higher mRNA concentration. The Ct value of the kinase gene is normalized by subtracting the Ct value of the β -2 microglobulin gene to obtain a Δ Ct value using the following formula: Δ Ct = Ct_{kinase} - Ct _{β -2 microglobulin}. Expression is then calibrated against a cDNA sample showing a comparatively low level of expression of the kinase gene. The Δ Ct value for the calibrator sample is then subtracted from Δ Ct for each tissue sample according to the following formula: $\Delta\Delta$ Ct = Δ Ct_{sample} - Δ Ct_{calibrator}. Relative expression is then calculated using the arithmetic formula given by $2^{-\Delta\Delta$ Ct}. Expression of the target gene in each of the tissues tested is then graphically represented as discussed in more detail below.

Figure 15Y depicts expression of TANGO 210 in various tissues and cell lines as described above, relative to expression in fetal heart tissue. The results indicate

significant expression in breast, skeletal muscle, colon, vein, aorta, testis, thyroid, and small intestine tissues.

Uses of TANGO 210 Nucleic acids,
5 Polypeptides, and Modulators Thereof

TANGO 210 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not expressed. Based on the observations that cDNA corresponding to TANGO 210 occurs in a human fetal skin cDNA library and in a murine long term bone marrow
10 cDNA library, and that RNA corresponding to TANGO 210 is detectable by Northern analysis of human adult and fetal kidney tissue, it is evident that TANGO 210 protein is involved in one or more biological processes which occur in these tissues. In particular, TANGO 210 is involved in modulating one or more of growth, proliferation, survival, differentiation, activity, morphology, and movement/migration of cells of
15 these tissues. TANGO 210 is involved in modulating the structure of extracellular matrix which contacts or is in fluid communication with cells of these tissues. Thus, TANGO 210 has a role in disorders which affect these cells and one or more of their growth, proliferation, survival, differentiation, activity, morphology, and movement/migration, as well as the biological function of organs comprising one or
20 more of these tissues.

The Northern analysis data described herein for human TANGO 210 indicate that nucleic acids corresponding to (i.e., homologous with or complementary to) all or part of human TANGO 210 cDNA or molecules (e.g., antibodies) which react specifically with human TANGO 210 protein or a portion thereof can be used to
25 identify kidney tissue or to differentiate kidney tissue from other types of tissue, such as heart, brain, placenta, lung, liver, and pancreas tissues. Thus, human TANGO 210 proteins, nucleic acids, and compounds which interact specifically with either of these, can be used for one or more of tissue typing, identification, and separation.

TANGO 210 gene expression data described herein indicate that TANGO 210 can be expressed in at least breast, skeletal muscle, colon, vein, aorta, testis, thyroid, small intestine, and spleen tissues. Thus, TANGO 210 can have a role in disorders which affect cells of these tissues and one or more of their growth, proliferation, survival, differentiation, activity, morphology, and movement/migration, as well as the biological function of organs comprising one or more of these tissues.

The fact that TANGO 210 is expressed in breast tissue is an indication that TANGO 210 can be involved in both normal physiological function of breast tissue and in breast disorders. Examples of breast disorders include breast cancer, insufficient lactation, infant nutritional and growth disorders, mastalgia, fibroadenomas, breast infections, and gynecomastia.

In another example, TANGO 210 polypeptides, nucleic acids, and modulators thereof, can be involved in normal and aberrant functioning of skeletal muscle tissue, and can thus be involved in disorders of such tissue. Examples of skeletal muscle disorders include muscular dystrophy (e.g., Duchenne muscular dystrophy, Becker muscular dystrophy, Emery-Dreifuss muscular dystrophy, limb-girdle muscular dystrophy, facioscapulohumeral muscular dystrophy, myotonic dystrophy, oculopharyngeal muscular dystrophy, distal muscular dystrophy, and congenital muscular dystrophy), motor neuron diseases (e.g., amyotrophic lateral sclerosis, infantile progressive spinal muscular atrophy, intermediate spinal muscular atrophy, spinal bulbar muscular atrophy, and adult spinal muscular atrophy), myopathies (e.g., inflammatory myopathies (e.g., dermatomyositis and polymyositis), myotonia congenita, paramyotonia congenita, central core disease, nemaline myopathy, myotubular myopathy, and periodic paralysis), and metabolic diseases of muscle (e.g., phosphorylase deficiency, acid maltase deficiency, phosphofructokinase deficiency, debrancher enzyme deficiency, mitochondrial myopathy, carnitine deficiency, carnitine palmityl transferase deficiency, phosphoglycerate kinase deficiency, phosphoglycerate mutase deficiency, lactate dehydrogenase deficiency, and myoadenylate deaminase deficiency). TANGO 210 polypeptides, nucleic acids, or modulators thereof can be

used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

5 In another example, TANGO 210 polypeptides, nucleic acids, and modulators thereof can be used to treat colonic disorders, such as those described elsewhere in this disclosure.

In another example, TANGO 210 polypeptides, nucleic acids, and modulators thereof, can be used to treat cardiovascular disorders, such as those described elsewhere in this disclosure.

10 In another example, TANGO 210 polypeptides, nucleic acids, or modulators thereof, can be used to treat testicular disorders, such as those described elsewhere in this disclosure.

TANGO 210 polypeptides, nucleic acids, and modulators thereof, can be involved in disorders of the thyroid gland, such as hyperthyroidism (e.g., diffuse toxic hyperplasia, toxic multi-nodular goiter, toxic adenoma, and acute or sub-acute
15 thyroiditis), hypothyroidism (e.g., cretinism and myxedema), thyroiditis (e.g., Hashimoto's thyroiditis, sub-acute granulomatous thyroiditis, sub-acute lymphocytic thyroiditis, Riedel's thyroiditis), Graves' disease, goiter (e.g., simple diffuse goiter and multi-nodular goiter), and tumors (e.g., adenoma, papillary carcinoma, follicular carcinoma, medullary carcinoma, undifferentiated malignant carcinoma, Hodgkin's
20 disease, and non-Hodgkin's lymphoma). TANGO 210 polypeptides, nucleic acids, or modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

In another example, TANGO 210 polypeptides, nucleic acids, and modulators thereof can be used to treat intestinal disorders (e.g., disorders of the small intestine),
25 such as ischemic bowel disease, infective enterocolitis, Crohn's disease, benign tumors, malignant tumors (e.g., argentaffinomas, lymphomas, adenocarcinomas, and sarcomas), malabsorption syndromes (e.g., celiac disease, tropical sprue, Whipple's disease, and abetalipoproteinemia), obstructive lesions, hernias, intestinal adhesions, intussusception, and volvulus.

TANGO 210 nucleic acids, proteins, and modulators thereof can be used to modulate proliferation, migration, morphology, differentiation, function, or some combination of these, of cells that form the spleen, (e.g., cells of the splenic connective tissue, splenic smooth muscle cells, or endothelial cells of the splenic blood vessels) or
5 of blood cells that are processed (e.g., regenerated, matured, or phagocytized) within the spleen, as described elsewhere in this disclosure.

There are several indications that TANGO 210 is an MMP. For instance, presence of each of a Peptidase_M10 domain, a zinc-binding domain signature, a hemopexin domain signature, and a cysteine switch in the amino acid sequences of
10 both human and murine TANGO 210 indicates that TANGO 210 exhibits extracellular matrix proteinase activity (e.g., collagenase and basement membrane degradative activities). In addition, homology between the sequence of human TANGO 210 and MMPs (e.g., MMP-8, as described herein) is a further indication the TANGO 210 is an MMP.

15 MMPs degrade extracellular matrix (ECM), and are thus involved in maintenance, and in renewal and replacement of old ECM with new ECM. ECM serves numerous purposes in the body, including providing support, containment, or both, to specialized tissues (e.g., tissues of organs such as skin, kidney, bone marrow, etc.) and regulating fluid balance in tissues which line a void or fluid-filled
20 compartment (e.g., skin, bladder, kidney, stomach, etc.). Demonstration, as described herein, that TANGO 210 is expressed in several of these tissues (fetal skin, bone marrow, kidney) indicates that TANGO 210 is involved in one or more of these processes.

An important function of kidney tissue is to regulate the volume and
25 composition of body fluids. The kidneys regulate body fluids by selectively permitting water, electrolytes, metabolites, and the like to pass from the plasma into the bladder in a regulatable manner while retaining cells and proteins in the plasma. By regulating fluid balance, the kidneys also exert a significant effect on arterial blood pressure. The kidneys perform these functions in a manner analogous to filtration.

Fluid outflow from the plasma occurs through the membranes of kidney glomerular capillaries in structures designated Bowman's capsules. The membrane of glomerular capillaries has three layers (normal capillaries have only two). Glomerular capillaries have a highly fenestrated luminal endothelium which can serve to prevent
5 passage of cells through the capillary membrane, but do not substantially inhibit passage of serum proteins. Surrounding the endothelium is an ECM basement membrane comprising collagen and peptidoglycan. An epithelial layer having gaps or channels through which glomerular filtrate is passed surrounds the basement membrane.

10 The basement membrane is the layer of the glomerular capillary membrane which is principally responsible for retention of serum proteins. In order to maintain proper operation of the kidneys, it is critical that the relative porosity of the basement membrane be maintained. Mineral precipitates, circulating bacteria, and the like can clog the pores of the basement membrane. Turnover, renewal, or controlled
15 degradation of the basement membrane ensures that the basement membrane remains functional. TANGO 210 is involved in regulating the thickness, porosity, and rate of degradation of the basement membrane of glomerular capillaries and other ECM components of kidney tissue. TANGO 210 is therefore involved in normal and abnormal formation and maintenance of functional kidney tissue. Thus, TANGO 210
20 is involved in a number of disorders which relate to aberrant kidney tissue formation and function. Such disorders include the kidney disorders described elsewhere herein. TANGO 210 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, treat, and inhibit one or more of these disorders.

25 Recovery of a cDNA encoding TANGO 210 from a murine long term bone marrow cDNA library indicates that TANGO 210 is expressed in bone marrow, and is thus involved both in normal physiological processes which occur in bone marrow and in disorders which affect bone marrow. ECM is a significant component of bone marrow, and TANGO 210 is involved in degradation of ECM associated with

turnover/renewal of bone marrow tissue, and with changes which occur in the bone marrow with age. As mammals age, the bone marrow becomes increasingly gelatinous and the ECM composition of the marrow changes. The cellular content of the bone marrow changes with time as well. In young mammals, most bones are filled with red marrow, which comprises large numbers of hematopoietic cells. As mammals age, red marrow is replaced by gelatinous, adipose cell-containing white and yellow marrows. TANGO 210 is involved in ECM changes which accompany age related changes in marrow composition. TANGO 210 is also involved in bone marrow-related disorders such as bone marrow failure (e.g., that associated with anemia) and rejection of heterologous implanted bone marrow. TANGO 210 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, treat, and inhibit one or more of these disorders. In addition, because TANGO 210 is associated with remodeling of bone marrow, TANGO 210 is also capable of modulating acceptance of donor bone marrow in a recipient.

Recovery of a cDNA encoding TANGO 210 from a human fetal skin cDNA library indicates that TANGO 210 is expressed in human skin, and is involved both in normal physiological processes which occur in skin and in skin disorders. Skin is a multi-layered tissue in which the various tissue layers can have different ECM compositions. Skin has a variety of roles in the normal mammal. Skin maintains the mechanical, osmotic, chemical, photic, and thermal integrity of the exterior surface of the mammal. TANGO 210, being expressed in the skin and able to modulate ECM composition, is therefore involved in regulating these characteristics in normal individuals and in individuals afflicted with disorders relating to aberrant regulation of these characteristics (e.g., ichthyosis). TANGO 210 is also involved in other disorders which occur in or affect ECM in skin. Such disorders include, by way of example, psoriasis, infections, wounds (and healing of wounds), inflammation, dermatitis, acne, benign and malignant dermatological tumors, and the like. TANGO 210 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either

of these can be used to prognosticate, diagnose, treat, and inhibit one or more of these disorders.

Numerous cancers are associated with aberrant MMP expression and activity. MMPs can aid cancer growth and metastasis by degrading ECM, thereby providing an avenue for angiogenesis, cell growth, or cell movement through a tissue. TANGO 210 is able to modulate the rate and extent of angiogenesis, and is therefore useful for prognosticating, diagnosing, treating, and inhibiting one or more disorders associated with aberrant angiogenesis, including, but not limited to cancers. Disorders associated with aberrant angiogenesis include both those associated with an abnormally high rate or extent of angiogenesis (e.g., cancerous growth and metastasis) and those associated with an abnormally or insufficiently low rate or extent of angiogenesis (e.g., impaired wound healing, transplanted tissue rejection, and acute and chronic ischemic disorders such as stroke). TANGO 210 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, treat, and inhibit one or more cancers or other disorders associated with aberrant angiogenesis.

TANGO 366

A cDNA clone (designated jthqc016c02) encoding at least a portion of human TANGO 366 protein was isolated from a human normal prostate fibroblast cDNA library by SPOT analysis. Human TANGO 366 protein is predicted by structural analysis to be a transmembrane protein.

The full length of the cDNA encoding human TANGO 366 protein (Figure 16; SEQ ID NO: 191) is 2628 nucleotide residues. The ORF of this cDNA, nucleotide residues 86 to 1144 of SEQ ID NO: 191 (i.e., SEQ ID NO: 192), encodes a 353-amino acid residue protein (Figure 16; SEQ ID NO: 193), corresponding to a 337-residue transmembrane protein.

The invention thus includes purified human TANGO 366 protein, both in the form of the immature 353 amino acid residue protein (SEQ ID NO: 193) and in the

form of the mature 337 amino acid residue protein (SEQ ID NO: 195). Mature human TANGO 366 proteins can be synthesized without the signal sequence polypeptide at the amino terminus thereof, or it can be synthesized by generating immature TANGO 366 protein and cleaving the signal sequence therefrom.

5 The invention includes nucleic acid molecules which encode a polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the nucleotide sequence listed in SEQ ID NO: 191 or some portion thereof, such as the portion which encodes mature human TANGO 366 protein, immature human TANGO 366 protein, or a domain of human TANGO 366 protein. These nucleic acids are
10 collectively referred to as nucleic acids of the invention.

TANGO 366 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional features.

A common domain present in TANGO 366 proteins is a signal sequence. In one embodiment, a TANGO 366 protein contains a signal sequence corresponding to
15 the portion of the protein from amino acid residue 1 to about amino acid residue 16 of SEQ ID NO: 193 (SEQ ID NO: 194). It is recognized that the carboxyl terminal boundary of the signal sequence can be located one or two residues from the residue identified above (i.e., at residue 14, 15, 16, 17, or 18 of SEQ ID NO: 193). The signal sequence is cleaved during processing of the mature protein.

20 TANGO 366 proteins can include an extracellular domain. The human TANGO 366 protein extracellular domain is located from about amino acid residue 17 to amino acid residue 216 of SEQ ID NO: 193 (i.e., the extracellular domain has the sequence SEQ ID NO: 196).

In addition, TANGO 366 can include a transmembrane domain. In one
25 embodiment, a TANGO 366 protein of the invention contains a transmembrane domain corresponding to about amino acid residues 217 to 239 of SEQ ID NO: 193 (i.e., the transmembrane domain has the sequence SEQ ID NO: 197).

The present invention includes TANGO 366 proteins having a cytoplasmic domain, particularly including proteins having a carboxyl-terminal cytoplasmic

domain. The human TANGO 366 cytoplasmic domain is located from about amino acid residue 240 to amino acid residue 353 of SEQ ID NO: 193 (i.e., the cytoplasmic domain has the sequence SEQ ID NO: 198).

In an alternative embodiment, TANGO 366 proteins can have a cytoplasmic domain located from about amino acid residue 17 to amino acid residue 216 of SEQ ID NO: 193 (i.e., the cytoplasmic domain has the sequence SEQ ID NO: 196); a transmembrane domain corresponding to about amino acid residues 217 to 239 of SEQ ID NO: 193 (i.e., the transmembrane domain has the sequence SEQ ID NO: 197); and an extracellular domain located from about amino acid residue 240 to amino acid residue 353 of SEQ ID NO: 193 (i.e., the extracellular domain has the sequence SEQ ID NO: 198)

TANGO 366 proteins typically comprise a variety of potential post-translational modification sites (often within an extracellular domain), such as those described herein in Table XII, as predicted by computerized sequence analysis of TANGO 366 proteins using amino acid sequence comparison software (comparing the amino acid sequence of TANGO 366 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}).

Table XII

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 193	Amino Acid Sequence
N-glycosylation site	74 to 77	NESV
	137 to 140	NLSH
Protein kinase C phosphorylation site	16 to 18	TTR
	67 to 69	SNR
	332 to 334	SPK
Casein kinase II phosphorylation site	40 to 43	TRVD
	280 to 283	SLQE

Table XII (Continued)

Tyrosine kinase phosphorylation site	318 to 325	RLVREGTY
N-myristoylation site	13 to 18	GAQTTR
	32 to 37	GLFDSF
	88 to 93	GLDLSH
	214 to 219	GNPLAV
	223 to 228	GAFAGL
Glycosaminoglycan attachment site	45 to 48	SGLG
Leucine rich repeat amino terminal (LRRNT) domain	19 to 58	See Fig. 16
Leucine rich repeat (LRR) domain	59 to 82	See Fig. 16
	85 to 108	
	109 to 132	
	133 to 155	
	185 to 206	
	207 to 229	
	230 to 254	
	255 to 279	
	280 to 303	
Leucine zipper pattern	284 to 305	See Fig. 16

In various embodiments, the protein of the invention has at least 1, 2, 4, 6, 10,
5 15, or 20 or more of the post-translational modification sites described herein in Table XII.

Examples of additional domains present in human TANGO 366 protein include a glycosaminoglycan attachment site, several leucine rich repeat (LRR and LRRNT) domains, and a leucine zipper domain. In one embodiment, the protein of the invention
10 has at least one domain that is at least 55%, preferably at least about 65%, more

preferably at least about 75%, yet more preferably at least about 85%, and most preferably at least about 95% identical to one of the LRR or leucine zipper domains described herein in Table XII. Preferably, the protein of the invention has at least one LRR domain, one leucine zipper domain, and one potential glycosaminoglycan attachment site sequence.

One or more LRR domains are present in a variety of proteins involved in protein-protein interactions. Such proteins include, for example, proteins involved in signal transduction, cell-to-cell adhesion, cell-to-extracellular matrix adhesion, cell development, DNA repair, RNA processing, and cellular molecular recognition processes. Specialized LRR domains, designated LRR amino terminal (LRRNT) domains often occur near the amino ends of a series of LRR domains. TANGO 366 protein has nine LRR domains, arranged in two groups, the first group including (from the amino terminus toward the carboxyl terminus of TANGO 366) the LRRNT domain and four LRR domains, and the second group including four LRR domains.

TANGO 366 is involved in one or more physiological processes in which these other LRR domain-containing proteins are involved, namely binding of cells with extracellular proteins such as soluble extracellular proteins and cell surface proteins of other cells.

TANGO 366 comprises a leucine zipper region at about amino acid residue 284 to about amino acid residue 305 (i.e., 284 LdlsgtnLvplpeaLllhlpaL 305; SEQ ID NO: 458). Leucine zipper regions are known to be involved in dimerization of proteins. Leucine zipper regions interact with one another, leading to formation of homo- or hetero-dimers between proteins, depending on their identity. Dimers of proteins having leucine zipper regions can also interact with DNA. The presence in TANGO 366 of a leucine zipper region is a further indication that this protein is involved in protein-protein interactions.

The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that human TANGO 366 protein includes an approximately 16 amino acid signal peptide (amino acid residues 1 to about 16 of SEQ

ID NO: 193; SEQ ID NO: 194) preceding the mature TANGO 366 protein (amino acid residues 17 to 353 of SEQ ID NO: 193; SEQ ID NO: 195). Human TANGO 366 protein includes an extracellular domain (amino acid residues 17 to 216 of SEQ ID NO: 193; SEQ ID NO: 196), a transmembrane domain (amino acid residues 217 to 239 of SEQ ID NO: 193; SEQ ID NO: 197), and a cytoplasmic domain (amino acid residues 240 to 353 of SEQ ID NO: 193; SEQ ID NO: 198).

Figure 16E depicts a hydrophobicity plot of human TANGO 366 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to about 16 of SEQ ID NO: 193 is the signal sequence of human TANGO 366 (SEQ ID NO: 194), and the hydrophobic region which corresponds to amino acid residues 217 to 239 of SEQ ID NO: 193 is the transmembrane region of TANGO 366 (SEQ ID NO: 197). As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human TANGO 366 protein from about amino acid residue 315 to about amino acid residue 330 appears to be located at or near the surface of the protein, while the region from about amino acid residue 290 to about amino acid residue 305 appears not to be located at or near the surface.

The predicted molecular weight of human TANGO 366 protein without modification and prior to cleavage of the signal sequence is about 37.8 kilodaltons. The predicted molecular weight of the mature human TANGO 366 protein without modification and after cleavage of the signal sequence is about 36.1 kilodaltons.

TANGO 366 exhibits limited sequence similarity to numerous cell surface proteins, including proteins which serve as cell surface antigens, proteoglycans, and protein receptors. TANGO 366 protein, cDNA, and ORF exhibit sequence homology to the sequences corresponding to a GENBANK™ record having Accession No. HSM800846. The nucleotide sequence of the DNA molecule described in GENBANK™ Accession No. HSM800846 is identical to nucleotide residues 418 to

2628 of SEQ ID NO: 191. The cDNA of GENBANK™ Accession No. HSM800846 was obtained from uterine tissue, indicating that TANGO 366 is expressed in uterine tissue and thus involved in normal and aberrant physiological processes in uterine tissue. In addition, nucleotide residues 36 to 319 of the reverse complement of SEQ ID NO: 191 exhibits significant homology with expressed sequence tag (EST) 01904, which is disclosed in an international patent application having PCT Publication No. WO93/16178. The ESTs described in that application were isolated from human brain tissue. This is an indication that TANGO 366 is expressed in brain tissue and thus is involved in normal and aberrant physiological processes in brain tissue.

Uses of TANGO 366 Nucleic acids,
Polypeptides, and Modulators Thereof

TANGO 366 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not expressed. Based on the observations that cDNA corresponding to TANGO 366 occurs in a human normal prostate fibroblast, brain, and uterus cDNA libraries, it is evident that TANGO 366 protein is involved in one or more biological processes which occur in prostate, brain, uterus, and other solid tissues. In particular, TANGO 366 is involved in modulating one or more of growth, proliferation, survival, differentiation, activity, morphology, and movement/migration of cells of prostate, brain, uterus, and other solid tissues. Thus, TANGO 366 has a role in disorders which affect the prostate, brain, uterus, and other solid tissues and one or more of growth, proliferation, survival, differentiation, activity, morphology, and movement/migration of cells in those tissues, as well as the biological function of organs (e.g., the prostate) comprising such tissues.

Disorders which affect the prostate include the prostate disorders described elsewhere in this disclosure. TANGO 366 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, treat, and inhibit one or more of these disorders.

Examples of brain disorders include the brain disorders described elsewhere in this disclosure. TANGO 366 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, treat, and inhibit one or more of these disorders.

5 Disorders which involve uterus tissue include the uterine disorders described elsewhere in this disclosure. TANGO 366 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, treat, and inhibit one or more of these disorders.

There are several indications that TANGO 366 is a cell surface protein which is
10 involved in binding a protein to the cell which expresses TANGO 366. For instance, presence in TANGO 366 of an amino terminal extracellular domain that includes an LRRNT and four LRR domains exemplifies the cell-surface protein interaction capability of TANGO 366. In addition, the amino acid sequence similarity which
TANGO 366 exhibits with respect to several other cell surface protein-binding proteins
15 reinforces this view. TANGO 366 is involved in binding an animal cell which expresses it with one or more of an extracellular fluid protein, a protein component of the extracellular matrix, a surface protein another cell of the same animal, and a surface protein of a bacterium, fungus, or virus. Thus, TANGO 366 is involved in modulating cell-to-cell adhesion, tissue and extracellular matrix invasivity of cells, infectivity of
20 cells by pathogens (e.g., bacteria and viruses), endocrine signaling processes, tissue developmental and organizational processes, and the like. TANGO 366 is involved in disorders in which these physiological processes are relevant. Such disorders include, for example, loss of control of cell growth, tumor metastasis, malformation of neurological connections, inflammation, immune and autoimmune responses, bacterial,
25 fungal, and viral infections, and the like. TANGO 366 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, treat, and inhibit one or more of these disorders.

INTERCEPT 394

A cDNA clone (designated jthKa041f02) encoding at least a portion of human INTERCEPT 394 protein was isolated from a human fetal kidney cDNA library.

Human INTERCEPT 394 protein is predicted by structural analysis to be a

5 transmembrane protein.

The full length of the cDNA encoding human INTERCEPT 394 protein (Figure 17; SEQ ID NO: 201) is 3743 nucleotide residues. The ORF of this cDNA, nucleotide residues 320 to 2653 of SEQ ID NO: 201 (i.e., SEQ ID NO: 202), encodes a 778-amino acid residue protein (Figure 17; SEQ ID NO: 203), corresponding to a 778-residue transmembrane protein. It is recognized that, in an alternative form, transcription of INTERCEPT 394 protein can be initiated at the ATG codon located at nucleotide residues 120-122 of SEQ ID NO 201. In this alternative form, INTERCEPT 394 protein has, at the amino-terminal end of SEQ ID NO: 203, an additional 61 amino acid residues, this additional portion having the amino acid sequence encoded by
10 nucleotide residues 120-319 of SEQ ID NO: 201. The sequences corresponding to the cDNA (SEQ ID NO: 217), ORF (SEQ ID NO: 215), and protein (SEQ ID NO: 216) of this alternate form are listed in Figures 17H through 17M. In the following discussion, molecules of the two forms of INTERCEPT 394 are referred to individually and collectively as molecules of the corresponding type (e.g., cDNA or protein).

20 The invention thus includes purified human INTERCEPT 394 protein, both in the form of the immature 778 amino acid residue protein (SEQ ID NO: 203) and in the form of the mature 753 amino acid residue protein (SEQ ID NO: 205). Mature human INTERCEPT 394 proteins can be synthesized without the signal sequence polypeptide at the amino terminus thereof, or it can be synthesized by generating immature
25 INTERCEPT 394 protein and cleaving the signal sequence therefrom.

The invention includes nucleic acid molecules which encode a polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the nucleotide sequence listed in SEQ ID NO: 201 or some portion thereof, such as the portion which encodes mature human INTERCEPT 394 protein, immature human

INTERCEPT 394 protein, or a domain of human INTERCEPT 394 protein. These nucleic acids are collectively referred to as nucleic acids of the invention.

INTERCEPT 394 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional features.

5 A common domain present in INTERCEPT 394 proteins is a signal sequence. In one embodiment, a INTERCEPT 394 protein contains a signal sequence corresponding to the portion of the protein from amino acid residue 1 to about amino acid residue 25 of SEQ ID NO: 203 (SEQ ID NO: 204). It is recognized that the carboxyl terminal boundary of the signal sequence can be located one or two residues
10 from the residue identified above (i.e., at residue 23, 24, 25, 26, or 27 of SEQ ID NO: 203). The signal sequence is cleaved during processing of the mature protein.

INTERCEPT 394 proteins can include an extracellular domain. Human INTERCEPT 394 protein extracellular domains are located at about amino acid residues 88 to 228 and 337 to 345 of SEQ ID NO: 203 (i.e., the extracellular domains
15 having the sequences SEQ ID NOs: 208 and 212, respectively).

In addition, INTERCEPT 394 can include a transmembrane domain. In one embodiment, a INTERCEPT 394 protein of the invention contains transmembrane domains corresponding to about amino acid residues 71 to 87, 229 to 253, 320 to 336, and 346 to 364 of SEQ ID NO: 203 (i.e., the transmembrane domains having the
20 sequences SEQ ID NOs: 207, 209, 211, and 213, respectively).

The present invention includes INTERCEPT 394 proteins having a cytoplasmic domain. The INTERCEPT 394 cytoplasmic domains are located from about amino acid residue 26 to 70, 254 to 319, and 365 to 778 of SEQ ID NO: 203 (i.e., the cytoplasmic domains having the sequences SEQ ID NOs: 206, 210, and 214,
25 respectively).

In an alternative form, INTERCEPT 394 proteins have cytoplasmic domains located at about amino acid residues 88 to 228 and 337 to 345 of SEQ ID NO: 203 (i.e., the cytoplasmic domains having the sequences SEQ ID NOs: 208 and 212, respectively); transmembrane domains corresponding to about amino acid residues 71

to 87, 229 to 253, 320 to 336, and 346 to 364 of SEQ ID NO: 203 (i.e., the transmembrane domains having the sequences SEQ ID NOs: 207, 209, 211, and 213, respectively); and extracellular domains located from about amino acid residue 26 to 70, 254 to 319, and 365 to 778 of SEQ ID NO: 203 (i.e., the extracellular domains
5 having the sequences SEQ ID NOs: 206, 210, and 214, respectively).

INTERCEPT 394 proteins typically comprise a variety of potential post-translational modification sites (often within an extracellular domain), such as those described herein in Table XIII, as predicted by computerized sequence analysis of INTERCEPT 394 proteins using amino acid sequence comparison software (comparing
10 the amino acid sequence of INTERCEPT 394 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}).

Table XIII

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 203	Amino Acid Sequence
N-glycosylation site	38 to 41	NHSL
	68 to 71	NGSL
	163 to 166	NKSL
	446 to 449	NFTV
cAMP-/cGMP-dependent protein kinase phosphorylation site	671 to 674	RRES
Protein kinase C phosphorylation site	62 to 64	SAR
	129 to 131	TQK
	207 to 209	SLK
	226 to 228	SNR
	568 to 570	SCR
	604 to 606	TGR

	527 to 532	GAAASL
	600 to 605	GQAPTG
	630 to 635	GQLQSL
	685 to 690	GGEGAR
	709 to 714	GAPETT
	752 to 757	GQSASR

In various embodiments, the protein of the invention has at least 1, 2, 4, 6, 10, 15, or 20 or more of the post-translational modification sites described herein in Table XIII.

5 The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that human INTERCEPT 394 protein includes an approximately 25 amino acid signal peptide (amino acid residues 1 to about 25 of SEQ ID NO: 203; SEQ ID NO: 204) preceding the mature INTERCEPT 394 protein (amino acid residues 26 to 778 of SEQ ID NO: 203; SEQ ID NO: 205). Human INTERCEPT
10 394 protein includes two extracellular domains (amino acid residues 88 to 228 and 337 to 345 of SEQ ID NO: 203; SEQ ID NOs: 208 and 212, respectively), four transmembrane domains (amino acid residues 71 to 87, 229 to 253, 320 to 336, and 346 to 364 of SEQ ID NO: 203; SEQ ID NOs: 207, 209, 211, and 213, respectively), and three cytoplasmic domains (amino acid residues 26 to 70, 254 to 319, and 365 to
15 778 of SEQ ID NO: 203; SEQ ID NOs: 206, 210, and 214, respectively).

 Figure 17G depicts a hydrophobicity plot of human INTERCEPT 394 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to about 25 of SEQ ID NO: 203 is the
20 signal sequence of human INTERCEPT 394 (SEQ ID NO: 204). Hydrophobic regions which corresponding to amino acid residues 71 to 87, 229 to 253, 320 to 336, and 346 to 364 of SEQ ID NO: 203 are the transmembrane regions of INTERCEPT 394 (SEQ ID NOs: 207, 209, 211, and 213, respectively). As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein,
25 and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human INTERCEPT 394 protein from about amino acid residue 205 to about amino acid residue 225 appears to be located at or near the surface of the protein, while the region from about amino acid

residue 410 to about amino acid residue 340 appears not to be located at or near the surface.

The predicted molecular weight of human INTERCEPT 394 protein without modification and prior to cleavage of the signal sequence is about 87.4 kilodaltons.

- 5 The predicted molecular weight of the mature human INTERCEPT 394 protein without modification and after cleavage of the signal sequence is about 84.5 kilodaltons. Nucleotide residues 2944 to 3482 of the reverse complement of SEQ ID NO: 201 exhibits significant homology with EST clone BJ38, which is disclosed in an international patent application having PCT Publication No. WO98/45435. The ESTs
10 described in that application were isolated from human tissues. This is an indication that INTERCEPT 394 is expressed in the same tissues as this EST clone and thus is involved in normal and aberrant physiological processes in these tissues.

- Uses of INTERCEPT 394 Nucleic acids,
15 Polypeptides, and Modulators Thereof

- INTERCEPT 394 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not expressed. Based on the observations that cDNA corresponding to INTERCEPT 394 occurs in a human fetal kidney cDNA library, it is evident that INTERCEPT 394
20 protein is involved in one or more biological processes which occur in kidney and other fetal and adult human tissues. In particular, INTERCEPT 394 is involved in modulating one or more of growth, proliferation, survival, differentiation, activity, morphology, and movement/migration of cells of kidney and other tissues. Thus, INTERCEPT 394 has a role in disorders which affect kidney and other tissues and one
25 or more of growth, proliferation, survival, differentiation, activity, morphology, and movement/migration of cells in those tissues, as well as the biological function of organs (e.g., the kidneys) comprising such tissues. Examples of kidney disorders are described elsewhere in this disclosure.

The relatively large size of the carboxyl-terminal cytoplasmic domain of INTERCEPT 394 is an indication that INTERCEPT 394 protein is involved in modulation of one or more intracellular processes. The presence of extracellular domains indicates that the activity of INTERCEPT 394 can be modulated by binding thereto of ligands (i.e., either naturally-occurring ligands or non-naturally-occurring ligands such as pharmaceutical agents). Because INTERCEPT 394 protein is an integral membrane protein, it is capable of exerting its physiological effect either by itself or in combination with one or more other membrane proteins. INTERCEPT 394 is thus involved in either or both of generation of signals which can be transmitted either to another protein (or other molecule) on the same side of the membrane or to a protein (or other molecule) on the opposite side of the membrane the membrane. INTERCEPT 394 can transmit such signals by binding a ligand, whereby its conformation is altered such that the ability of INTERCEPT 394 to interact with another molecule (e.g., to catalyze a reaction involving the molecule or by binding with the molecule) is altered upon binding the ligand. Alternatively, INTERCEPT 394 can be altered by being post-translationally modified (e.g., phosphorylated, glycosylated, or myristoylated) such that the ability of INTERCEPT 394 to interact with another molecule is altered upon post-translational modification.

Involvement of INTERCEPT 394 in one or more signal transmission pathways is an indication that INTERCEPT 394 is involved in physiological pathways involving such transmission. Thus, INTERCEPT 394 is also involved in disorders which involve these signal transmission pathways. Examples of physiological pathways that involve signal transmission include cell nutrition and metabolism, cell proliferation, cell differentiation, apoptosis, chemotactic and chemokinetic activities, cell aggregation and attachment, cell movement, immune stimulation, hematopoiesis, metastasis, and the like. INTERCEPT 394 is thus involved in disorders relating to aberrant activity of one or more of these signal transmission pathways. Such disorders include, for example, carcinogenesis, tumor growth, tumor metastasis, angiogenesis, apoptosis, inappropriate blood coagulation (e.g., that involved in atherosclerosis, arteriosclerosis,

and stroke), immune hypo- and hyper-stimulation, cell metabolism disorders (e.g., diabetes), endocrine disorders (e.g., hypo- and hyper-thyroidism), mineral import and export disorders (e.g., osteoporosis, kidney stone formation, and hemochromatosis), and the like.

5 Presence of INTERCEPT 394 in the membrane of cells in which it is expressed indicates that INTERCEPT 394 can be used as a diagnostic target for detection or imaging of such cells. Furthermore, a portion of INTERCEPT 394 (e.g., an extracellular domain) can be used to interfere with binding of a virus which normally binds with INTERCEPT 394, thereby inhibiting, reducing, or eliminating pathological
10 effects associated with infection of a human by the virus.

INTERCEPT 400

A cDNA clone (designated jthkf014a09) encoding at least a portion of human INTERCEPT 400 protein was isolated from a human normal embryonic keratinocyte
15 cDNA library. A corresponding murine cDNA clone (designated jtmbs232b12) was isolated from a brain polysome cDNA library. Human and murine INTERCEPT 400 proteins are predicted by structural analysis to be transmembrane proteins.

The full length of the cDNA encoding human INTERCEPT 400 protein (Figure 18; SEQ ID NO: 221) is 2989 nucleotide residues. The open reading frame (ORF) of
20 this cDNA, nucleotide residues 206 to 1000 of SEQ ID NO: 221 (i.e., SEQ ID NO: 222), encodes a 265-amino acid residue immature protein (Figure 18; SEQ ID NO: 223), corresponding to a 219-residue transmembrane protein.

The invention thus includes purified human INTERCEPT 400 protein, both in the form of the immature 265 amino acid residue protein (SEQ ID NO: 223) and in the
25 form of the mature 219 amino acid residue protein (SEQ ID NO: 225). The invention also includes purified murine INTERCEPT 400 protein, which is a 180-amino acid residue transmembrane protein (SEQ ID NO: 243). Mature human INTERCEPT 400 proteins can be synthesized without the signal sequence polypeptide at the amino

terminus thereof, or it can be synthesized by generating immature INTERCEPT 400 protein and cleaving the signal sequence therefrom.

The invention includes nucleic acid molecules which encode a polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the
5 nucleotide sequence listed in SEQ ID NO: 221 or some portion thereof or SEQ ID NO: 241 or some portion thereof, such as the portion which encodes mature human or murine INTERCEPT 400 protein, immature human INTERCEPT 400 protein, or a domain of human or murine INTERCEPT 400 protein. These nucleic acids are collectively referred to as nucleic acids of the invention.

10 INTERCEPT 400 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional features.

A common domain present in INTERCEPT 400 proteins is a signal sequence. In one embodiment, a INTERCEPT 400 protein contains a signal sequence corresponding to the portion of the protein from amino acid residue 1 to about amino
15 acid residue 46 of SEQ ID NO: 223 (SEQ ID NO: 224). It is recognized that the carboxyl terminal boundary of the signal sequence can be located one or two residues from the residue identified above (i.e., at residue 44, 45, 46, 47, or 48 of SEQ ID NO: 223). The signal sequence is cleaved during processing of the mature protein.

INTERCEPT 400 proteins can also include an extracellular domain. Human
20 INTERCEPT 400 protein includes extracellular domains located from about amino acid residues 47 to 62, 154 to 164, and 218 to 231 of SEQ ID NO: 223 (i.e., the extracellular domains having the amino acid sequences SEQ ID NOs: 226, 230, and 234, respectively). Murine INTERCEPT 400 protein includes extracellular domains located from about amino acid residues 61 to 71 and 125 to 140 of SEQ ID NO: 243
25 (i.e., these extracellular domains having the amino acid sequences SEQ ID NOs: 246 and 250, respectively).

In addition, INTERCEPT 400 can include a transmembrane domain. Human INTERCEPT 400 protein includes transmembrane domains corresponding to about amino acid residues 63 to 79, 137 to 153, 165 to 183, 194 to 217, and 232 to 251 of

SEQ ID NO: 223 (i.e., the transmembrane domains having the sequences SEQ ID NOs: 227, 229, 231, 233, and 235, respectively). Murine INTERCEPT 400 protein includes transmembrane domains corresponding to about amino acid residues 44 to 60, 72 to 90, 101 to 124, and 141 to 160 of SEQ ID NO: 243 (i.e., the transmembrane domains
5 having the sequences SEQ ID NOs: 245, 247, 249, and 251, respectively).

The present invention includes INTERCEPT 400 proteins having a cytoplasmic domain. Human INTERCEPT 400 cytoplasmic domains are located from about amino acid residue 80 to 136, 184 to 193, and 252 to 265 of SEQ ID NO: 223 (i.e., the cytoplasmic domains having the sequences SEQ ID NOs: 228, 232, and 236,
10 respectively). Murine INTERCEPT 400 cytoplasmic domains are located from about amino acid residue 1 to 43, 91 to 100, and 161 to 174 of SEQ ID NO: 243 (i.e., the cytoplasmic domains having the sequences SEQ ID NOs: 244, 248, and 252, respectively).

It is recognized that, in one form, murine INTERCEPT 400 protein can include
15 an amino terminal portion approximately 60-120 (likely 80-100) amino acid residues in length.

In an alternative embodiment, human INTERCEPT 400 proteins have cytoplasmic domains located from about amino acid residues 47 to 62, 154 to 164, and 218 to 231 of SEQ ID NO: 223 (i.e., the cytoplasmic domains having the amino acid
20 sequences SEQ ID NOs: 226, 230, and 234, respectively); transmembrane domains corresponding to about amino acid residues 63 to 79, 137 to 153, 165 to 183, 194 to 217, and 232 to 251 of SEQ ID NO: 223 (i.e., the transmembrane domains having the sequences SEQ ID NOs: 227, 229, 231, 233, and 235, respectively); and extracellular domains are located from about amino acid residue 80 to 136, 184 to 193, and 252 to
25 265 of SEQ ID NO: 223 (i.e., the extracellular domains having the sequences SEQ ID NOs: 228, 232, and 236, respectively).

In an alternative embodiment, murine INTERCEPT 400 proteins have cytoplasmic domains located from about amino acid residues 61 to 71 and 125 to 140 of SEQ ID NO: 243 (i.e., these cytoplasmic domains having the amino acid sequences

SEQ ID NOs: 246 and 250, respectively); transmembrane domains corresponding to about amino acid residues 44 to 60, 72 to 90, 101 to 124, and 141 to 160 of SEQ ID NO: 243 (i.e., the transmembrane domains having the sequences SEQ ID NOs: 245, 247, 249, and 254, respectively); and extracellular domains are located from about
5 amino acid residue 1 to 43, 91 to 100, and 161 to 174 of SEQ ID NO: 243 (i.e., the extracellular domains having the sequences SEQ ID NOs: 244, 248, and 255, respectively).

INTERCEPT 400 proteins typically comprise a variety of potential post-translational modification sites (often within an extracellular domain), such as those
10 described herein in Tables XIV (for human INTERCEPT 400) and XV (for murine INTERCEPT 400), as predicted by computerized sequence analysis of INTERCEPT 400 proteins using amino acid sequence comparison software (comparing the amino acid sequence of INTERCEPT 400 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}).

15

Table XIV

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 223	Amino Acid Sequence
N-glycosylation site	2 to 5	NMSV
cAMP-/cGMP-dependent protein kinase phosphorylation site	259 to 262	RKTT
Protein kinase C phosphorylation site	155 to 157	SYK

	98 to 100	SRK
Casein kinase II phosphorylation site	4 to 7	SVCD
	62 to 65	SYKD
	171 to 174	TKAE
N-myristoylation site	116 to 121	GCVINY

5

In various embodiments, the protein of the invention has at least 1, 2, 4, 6, 10, 15, or 20 or more of the post-translational modification sites described herein in Tables XIV and XV.

The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that human INTERCEPT 400 protein includes an approximately 46 amino acid signal peptide (amino acid residues 1 to about 46 of SEQ ID NO: 223; SEQ ID NO: 224) preceding the mature INTERCEPT 400 protein (amino acid residues 47 to 265 of SEQ ID NO: 223; SEQ ID NO: 225). Human INTERCEPT 400 protein includes three extracellular domains (amino acid residues 47 to 62, 154 to 164, and 218 to 231 of SEQ ID NO: 223; SEQ ID NOs: 226, 230, and 234, respectively), five transmembrane domains (amino acid residues 63 to 79, 137 to 153,

165 to 183, 194 to 217, and 232 to 251 of SEQ ID NO: 223; SEQ ID NOs: 227, 229, 231, 233, and 235, respectively), and three intracellular domains (amino acid residues 80 to 136, 184 to 193, and 252 to 265 of SEQ ID NO: 223; SEQ ID NOs: 228, 232, and 236, respectively).

5 Figure 18D depicts a hydrophobicity plot of human INTERCEPT 400 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to about 46 of SEQ ID NO: 223 is the signal sequence of human INTERCEPT 400 (SEQ ID NO: 224). As described
10 elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human INTERCEPT 400 protein from about amino acid residue 218 to about amino acid residue 231 appears to be located at or near the surface of the protein, while the region from about amino acid
15 residue 80 to about amino acid residue 95 appears not to be located at or near the surface.

The predicted molecular weight of human INTERCEPT 400 protein without modification and prior to cleavage of the signal sequence is about 31.4 kilodaltons. The predicted molecular weight of the mature human INTERCEPT 400 protein without
20 modification and after cleavage of the signal sequence is about 25.8 kilodaltons.

Human INTERCEPT 400 exhibits sequence similarity to murine Cig30 protein (GENBANK™ Accession No. U97107), as indicated herein in Figure 18L, which lists an alignment (made using the ALIGN software; pam120.mat scoring matrix; gap penalties -12/-4) of the amino acid sequences of these proteins. Figures 18M through
25 18O depict an alignment (also made using the ALIGN software; pam120.mat scoring matrix; gap penalties -12/-4) of the nucleotide sequences of the ORFs of human INTERCEPT 400 (SEQ ID NO: 222) and Cig30 (SEQ ID NO: 238). In these alignments (made using the ALIGN software; pam120.mat scoring matrix, gap penalties -12/-4), the amino acid sequences of these two proteins are 43.3% identical

and the ORF nucleotide sequences corresponding to these two proteins are 56.8% identical. The cDNAs corresponding to these two proteins were found to be 48.4% identical using the LALIGN software (pam120.mat scoring matrix; gap penalties -12/-4).

5 The length of the incomplete cDNA encoding the carboxyl-terminal portion of murine INTERCEPT 400 protein (Figure 18; SEQ ID NO: 241) is 2032 nucleotide residues. The ORF of this cDNA, nucleotide residues 3 to 524 (SEQ ID NO: 242), encodes a protein comprising at least 180 amino acid residues (Figure 18; SEQ ID NO: 243). It is recognized that murine INTERCEPT 400 protein has about 60-120, more
10 likely 80-100, additional amino acid residues at the amino terminal end thereof.

 The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that the portion of murine INTERCEPT 400 protein described herein includes at least two extracellular domains (amino acid residues 61 to 71 and 125 to 140 of SEQ ID NO: 243; SEQ ID NOs: 246 and 250, respectively), at
15 least four transmembrane domains (amino acid residues 44 to 60, 72 to 90, 101 to 124, and 141 to 160 of SEQ ID NO: 243; SEQ ID NOs: 245, 247, 249, and 254, respectively), and at least three cytoplasmic domains (amino acid residue 1 to 43, 91 to 100, and 161 to 174 of SEQ ID NO: 243; SEQ ID NOs: 244, 248, and 255, respectively).

20 Figure 18G depicts a hydrophobicity plot of murine INTERCEPT 400 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. Hydrophobic regions corresponds to the identified transmembrane regions of murine INTERCEPT 400. As described elsewhere herein, relatively hydrophilic regions are generally located at or
25 near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region from about amino acid residue 125 to about amino acid residue 140 appears to be located at or near the surface of the protein, while the region from about amino acid residue 14 to about amino acid residue 19 appears not to be located at or near the surface

The predicted molecular weight of the portion of murine INTERCEPT 400 protein described herein is about 20.6 kilodaltons.

Human and murine INTERCEPT 400 proteins exhibit considerable sequence similarity, as indicated herein in Figures 18H through 18K. Figure 18H depicts an alignment of human and murine INTERCEPT 400 amino acid sequences (SEQ ID NOs: 223 and 243, respectively). In this alignment (made using the ALIGN software; pam120.mat scoring matrix; gap penalties -12/-4), the proteins are 94.8% identical in the overlapping region (i.e., 163 identical residues out of 172 residues in the overlapping region, which includes amino acid residues 94-265 of SEQ ID NO: 223 and amino acid residues 1-174 of SEQ ID NO: 243). The human and murine ORFs encoding INTERCEPT 400 are 92.8% identical in the overlapping portions (i.e., nucleotide residues 280-795 of SEQ ID NO: 222 and nucleotide residues 1-522 of SEQ ID NO: 242), as assessed using the same software and parameters and as indicated in Figures 18I through 18K in an alignment made using the ALIGN software (pam120.mat scoring matrix; gap penalties -12/-4).

The partial nucleotide sequences of a rat cDNA clone (designated jtmba232b12; SEQ ID NO: 251) and ORF (SEQ ID NO: 252) encoding INTERCEPT 400 are depicted in Figures 18P and 18Q, together with the amino acid sequence (SEQ ID NO: 253) of the portion of the protein encoded by these nucleic acids. An alignment (made using the ALIGN software; pam120.mat scoring matrix; gap penalties -12/-4) of human, murine and rat INTERCEPT 400 amino acid sequences is listed in Figure 18R.

Uses of INTERCEPT 400 Nucleic acids, Polypeptides, and Modulators Thereof

INTERCEPT 400 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not expressed. Based on the observations that cDNA corresponding to INTERCEPT 400 occurs in a human normal embryonic keratinocyte cDNA library and in a murine brain polysome cDNA library, it is evident that INTERCEPT 400 protein is involved in one

or more biological processes which occur in these tissues. In particular, INTERCEPT 400 is involved in modulating one or more of growth, proliferation, survival, differentiation, activity, morphology, and movement/migration of cells of these tissues. INTERCEPT 400 is involved in modulating the structure of extracellular matrix which contacts or is in fluid communication with cells of these tissues. Thus, INTERCEPT 400 has a role in disorders which affect these cells and one or more of their growth, proliferation, survival, differentiation, activity, morphology, and movement/migration, as well as the biological function of organs comprising one or more of these tissues.

Examples of brain disorders are described elsewhere in this disclosure.

INTERCEPT 400 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, treat, and inhibit one or more of these disorders.

Examples of skin disorders with which INTERCEPT 400 can be associated are described elsewhere in this disclosure. INTERCEPT 400 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, treat, and inhibit one or more of these disorders.

Murine Cig30 protein, with which human INTERCEPT 400 shares significant amino acid sequence homology, is an integral membrane protein that is involved in recruitment and thermogenesis in brown adipose tissue in mice (Tvrdik et al., 1997, J. Biol. Chem. 272:31738-31746). Yeast proteins which share significant homology with murine Cig30 and human, murine, and rat INTERCEPT 400 protein include proteins encoded by yeast genes SUR4 (APA1) and FEN1 (GNS1). These proteins are involved in phospholipid metabolism, sterol synthesis, budding, activation of glucose-regulated genes, glucose uptake, and glucan synthesis (Desfarges et al., 1993, Yeast 9:267-277; Silve et al., 1996, Mol. Cell. Biol. 16:2719-2727; Durrens et al., 1995, Curr. Genet. 27:213-216; Garcia-Arranz, 1994, J. Biol. Chem. 269:18076-18082; El-Sherbeini et al., 1995, J. Bacteriol. 177:3227-3234). These activities relate to remodeling of the plasma membrane and actin cytoskeleton in response to growth signals, most likely by modulating interaction between membrane phospholipids and

the cytoskeleton. Thus, INTERCEPT 400 protein is involved in one or more of these activities, such as in immune stimulation, proliferation of leukocytes, generation and prolongation of an immune response, control of cellular metabolic processes, and the like.

5 INTERCEPT 400 is involved in generation, accumulation, and regulation of brown adipose tissue and other adipose tissues in humans, and is therefore involved in body temperature regulation, lipid metabolism, carbohydrate metabolism, body weight regulation, and the like. Thus, INTERCEPT 400 is implicated in disorders which relate to aberrance or imbalance in the normal physiological regulation of these
10 processes. INTERCEPT 400 is also involved in disorders which relate to aberrant proliferation and growth of cells. Examples of disorders in which INTERCEPT 400 is involved include obesity, unusual susceptibility or insensitivity to heat or cold, diabetes, arteriosclerosis, atherosclerosis, cancer, hypo- and hyper-immune disorders (e.g., acquired immune deficiency syndrome and auto-immune disorders), immune
15 proliferation, and the like. INTERCEPT 400 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, treat, and inhibit one or more of these disorders.

Chromosomal mapping data have been used to locate the gene encoding human INTERCEPT 400 at chromosome 4, between markers D4S1616 and D4S1611 (115.8-
20 119.6 centimorgans). A form of iris hypoplasia associated with early onset glaucoma has been linked with this chromosomal region. Human INTERCEPT 400 allelic variants can include INTERCEPT 400 nucleotide sequence polymorphisms (e.g., nucleotide sequences that vary from SEQ ID NO: 221) that map to this chromosomal region.

25

INTERCEPT 217

A cDNA clone (designated jthqc035f08) encoding at least a portion of human INTERCEPT 217 protein was isolated from a human prostate cDNA library. The human INTERCEPT 217 protein is predicted by structural analysis to be a

5 transmembrane protein. In addition, cDNA clones (including those designated jtmca047g07, jTmob373b05, and jambd078d12) encoding at least a portion of murine INTERCEPT 217 protein were isolated from murine cDNA libraries.

The full length of the cDNA encoding human INTERCEPT 217 protein (Figure 19; SEQ ID NO: 271) is 2895 nucleotide residues. The ORF of this cDNA, nucleotide
10 residues 215 to 1579 of SEQ ID NO: 271 (i.e., SEQ ID NO: 272), encodes a 455-amino acid transmembrane protein (Figure 19; SEQ ID NO: 273). The murine ORF (Figure 19; SEQ ID NO: 362) comprises at least 962 nucleotide residues. The protein encoded by the murine ORF comprises at least 320 amino acid residues (i.e., SEQ ID NO: 363), and is also a transmembrane protein.

15 The invention also includes purified human INTERCEPT 217 protein, both in the form of the immature 455 amino acid residue protein (SEQ ID NO: 273) and in the form of the mature, approximately 435 amino acid residue protein (SEQ ID NO: 275). Mature human INTERCEPT 217 protein can be synthesized without the signal sequence polypeptide at the amino terminus thereof, or it can be synthesized by
20 generating immature INTERCEPT 217 protein and cleaving the signal sequence therefrom.

The invention thus includes purified murine INTERCEPT 217 protein, both in the immature form comprising the 320 amino acid residues of SEQ ID NO: 363 and in the mature form comprising the approximately 305 carboxyl terminal amino acid
25 residues of SEQ ID NO: 363 (i.e., comprising SEQ ID NO: 365). Mature murine INTERCEPT 217 protein can be synthesized without the signal sequence polypeptide at the amino terminus thereof, or it can be synthesized by generating immature INTERCEPT 217 protein and cleaving the signal sequence therefrom.

The invention includes nucleic acid molecules which encode an INTERCEPT 217 polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the nucleotide sequence listed in SEQ ID NO: 271, in SEQ ID NO: 362 (i.e., the murine ORF), or in some portion of either of these, such as the portion
5 which encodes mature human INTERCEPT 217 protein, immature human INTERCEPT 217 protein, or a domain of human INTERCEPT 217 protein. These nucleic acids are collectively referred to as INTERCEPT 217 nucleic acids of the invention.

INTERCEPT 217 proteins and nucleic acid molecules encoding them comprise
10 a family of molecules having certain conserved structural and functional features. Each of these molecules is included in the invention.

A common domain present in INTERCEPT 217 proteins is a signal sequence. In one embodiment, a INTERCEPT 217 protein contains a signal sequence corresponding to about amino acid residues 1 to 20 of SEQ ID NO: 273 (SEQ ID NO:
15 274). The signal sequence is cleaved during processing of the mature protein.

INTERCEPT 217 proteins can include an extracellular domain. The human INTERCEPT 217 protein extracellular domain is located from about amino acid residue 21 to about amino acid residue 383 of SEQ ID NO: 273 (SEQ ID NO: 276). The murine INTERCEPT 217 protein extracellular domain is located from about amino
20 acid residue 17 to about amino acid residue 213 of SEQ ID NO: 363 (SEQ ID NO: 366).

In addition, INTERCEPT 217 includes a transmembrane domain. As used herein, a "transmembrane domain" refers to an amino acid sequence which is at least about 20 to 25 amino acid residues in length and which contains at least about 65-70%
25 hydrophobic amino acid residues such as alanine, leucine, phenylalanine, protein, tyrosine, tryptophan, or valine. In a preferred embodiment, a transmembrane domain contains at least about 15 to 30 amino acid residues, preferably about 20-25 amino acid residues, and has at least about 60-80%, more preferably 65-75%, and more preferably at least about 70% hydrophobic residues. Thus, in one embodiment, an INTERCEPT

217 protein of the invention contains a transmembrane domain corresponding to about amino acid residues 384 to 403 of SEQ ID NO: 273 (SEQ ID NO: 277) or to about amino acid residues 214 to 233 of SEQ ID NO: 363 (SEQ ID NO: 367).

5 The present invention includes INTERCEPT 217 proteins having a cytoplasmic domain, particularly including proteins having a carboxyl-terminal cytoplasmic domain. The human INTERCEPT 217 cytoplasmic domain is located from about amino acid residue 404 to amino acid residue 455 of SEQ ID NO: 273 (SEQ ID NO: 278). The murine INTERCEPT 217 cytoplasmic domain is located from about amino acid residue 234 to amino acid residue 320 of SEQ ID NO: 363 (SEQ ID NO: 368).

10 In one embodiment, the amino acid residues of human INTERCEPT 217 corresponding to SEQ ID NO: 278 are part of an extracellular domain, and the amino acid residues corresponding to SEQ ID NO: 276 are part of a cytoplasmic domain. In another embodiment, the amino acid residues of murine INTERCEPT 217 corresponding to SEQ ID NO: 368 are part of an extracellular domain, and the amino acid residues corresponding to SEQ ID NO: 366 are part of a cytoplasmic domain.

15 INTERCEPT 217 proteins typically comprise a variety of potential post-translational modification sites (often within an extracellular domain), such as those described herein in Tables XVIA (for human INTERCEPT 217) and XVIB (for murine INTERCEPT 217), as predicted by computerized sequence analysis of INTERCEPT 20 217 proteins using amino acid sequence comparison software (comparing the amino acid sequence of INTERCEPT 217 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}). In certain embodiments, a protein of the invention has at least 1, 2, 4, 6, or 10 or more of the post-translational modification sites listed in Tables XVIA and XVIB.

25

Table XVIA

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 273	Amino Acid Sequence
N-glycosylation site	107 to 110	NASG
	272 to 275	NCSS
	301 to 304	NTSV
	362 to 365	NQTH
	368 to 371	NVSV
Protein kinase C phosphorylation site	120 to 122	TLR
	192 to 194	SNR
	295 to 297	SLR
Casein kinase II phosphorylation site	199 to 202	SVPE
	440 to 443	TPPD
Tyrosine Kinase Phosphorylation Site	282 to 289	KRPEEHLY
N-myristoylation site	8 to 13	GTLLCM
	19 to 24	GTPDSE
	103 to 108	GVFVNA
	179 to 184	GLSATH
	323 to 328	GSRDGS
	348 to 353	GLFVCL
	390 to 395	GCAVGL
	449 to 454	GQASTS
Leucine zipper pattern	45 to 66	See Fig. 19
Leucine rich repeat amino terminal domain (LLRNT)	33 to 61	See Fig. 19

Immunoglobulin Domain	14 to 37	See Fig. 19
Leucine rich repeat (LRR) Domain	49 to 104	See Fig. 19
Leucine rich repeat carboxyl terminal (LLRCT) domain	123 to 184	See Fig. 19

Among the domains that occur in INTERCEPT 217 proteins are LRR domains,
5 LRRNT domains, LRRCT domains, and immunoglobulin domains. In one
embodiment, the protein of the invention has at least one domain that is at least 55%,
preferably at least about 65%, more preferably at least about 75%, yet more preferably
at least about 85%, and most preferably at least about 95% identical to one of these
domains. In other embodiments, the protein has at least one of each of the LRR,
10 LRRNT, and LRRCT domains described herein in Tables XVIA and XVIB. In other
embodiments, the protein has at least one LRRNT domain, at least one LRRCT
domain, and a plurality of (e.g., 2, 3, 4, or more) LRR domains.

One or more LRR domains are present in a variety of proteins involved in
protein-protein interactions. Such proteins include, for example, proteins involved in
15 signal transduction, cell-to-cell adhesion, cell-to-extracellular matrix adhesion, cell
development, DNA repair, RNA processing, and cellular molecular recognition
processes. Specialized LRR domains, designated LRR amino terminal (LRRNT)
domains and LRR carboxyl terminal (LRRCT) domains often occur near the amino and
carboxyl, respectively, ends of a series of LRR domains. Human INTERCEPT 217
20 protein has eight clustered LRR domains, including (from the amino terminus toward
the carboxyl terminus of INTERCEPT 217) an LRRNT domain, six LRR domains, and
an LRRCT domain.

The organization of LRR domains in human INTERCEPT 217 protein closely mirrors the organization of LRR domains in human platelet glycoprotein IB alpha chain precursor (GP-IB α), which also has eight clustered LRR domains from about amino acid residue 19 to about amino acid residue 281 thereof. The eight LRR domains of GP-IB α include an LRRNT domain at the end of the cluster nearest the amino terminus of GP-IB α and an LRRCT domain at the end of the cluster nearest the carboxyl terminus of GP-IB α . GP-IB α is a membrane-bound protein of human platelets that is involved in binding of von Willebrand's factor and in aggregation of platelets during thrombus formation. Thus, INTERCEPT 217 is involved in both normal and aberrant physiological activities involving blood clotting and thrombus formation. Examples of disorders involving such activities include, for example, stroke, embolism (e.g., cerebral, renal, and pulmonary emboli), hemophilia, restenotic injury, prosthesis-associated thrombogenesis, atherosclerosis, and arteriosclerosis.

INTERCEPT 217 is involved in one or more physiological processes in which these other LRR domain-containing proteins are involved, namely binding of cells with extracellular proteins such as soluble extracellular proteins and cell surface proteins of other cells.

Human INTERCEPT 217 comprises a leucine zipper region at about amino acid residue 45 to about amino acid residue 66 (i.e., 45 LsctglgLqdvpaELpaa tadL 66; SEQ ID NO: 459). Leucine zipper regions are known to be involved in dimerization of proteins. Leucine zipper regions interact with one another, leading to formation of homo- or hetero-dimers between proteins, depending on their identity. The presence in INTERCEPT 217 of a leucine zipper region is a further indication that this protein is involved in protein-protein interactions.

The amino acid sequence of human INTERCEPT 217 protein includes multiple potential proline-rich Src homology 3 (SH3) domain binding sites in the cytoplasmic portion of the protein. SH3 domains mediate specific assembly of protein complexes, presumably by interacting with proline-rich protein domains (Morton and Campbell (1994) Curr. Biol. 4:615-617). SH3 domains also mediate interactions between

proteins involved in transmembrane signal transduction. Coupling of proteins mediated by SH3 domains has been implicated in a variety of physiological systems, including those involving regulation of cell growth and proliferation, endocytosis, and activation of respiratory burst.

5 SH3 domains have been described in the art (e.g., Mayer et al. (1988) *Nature* 332:272-275; Musacchio et al. (1992) *FEBS Lett.* 307:55-61; Pawson and Schlessinger (1993) *Curr. Biol.* 3:434-442; Mayer and Baltimore (1993) *Trends Cell Biol.* 3:8-13; Pawson (1993) *Nature* 373:573-580), and occur in a variety of cytoplasmic proteins, including several (e.g., protein tyrosine kinases) involved in transmembrane signal
10 transduction. Among the proteins in which one or more SH3 domains occur are protein tyrosine kinases such as those of the Src, Abl, Bkt, Csk and ZAP70 families, mammalian phosphatidylinositol-specific phospholipases C-gamma-1 and -2, mammalian phosphatidylinositol 3-kinase regulatory p85 subunit, mammalian Ras GTPase-activating protein (GAP), proteins which mediate binding of guanine
15 nucleotide exchange factors and growth factor receptors (e.g., vertebrate GRB2, *Caenorhabditis elegans* sem-5, and *Drosophila* DRK proteins), mammalian Vav oncoprotein, guanidine nucleotide releasing factors of the CDC 25 family (e.g., yeast CDC25, yeast SCD25, and fission yeast ste6 proteins), MAGUK proteins (e.g., mammalian tight junction protein ZO-1, vertebrate erythrocyte membrane protein p55,
20 *C. elegans* protein lin-2, rat protein CASK, and mammalian synaptic proteins SAP90/PSD-95, CHAPSYN-110/PSD-93, SAP97/DLG1, and SAP102), proteins which interact with vertebrate receptor protein tyrosine kinases (e.g., mammalian cytoplasmic protein Nck and oncoprotein Crk), chicken Src substrate p80/85 protein (cortactin), human hemopoietic lineage cell specific protein Hs1, mammalian
25 dihydrouridine-sensitive L-type calcium channel beta subunit, human myasthenic syndrome antigen B (MSYB), mammalian neutrophil cytosolic activators of NADPH oxidase (e.g., p47 {NCF-1}, p67 {NCF-2}, and *C. elegans* protein B0303.7), myosin heavy chains (MYO3) from amoebae, from slime molds, and from yeast, vertebrate and *Drosophila* spectrin and fodrin alpha chain proteins, human amphiphysin, yeast

actin-binding proteins ABP1 and SLA3, yeast protein BEM1, fission yeast protein scd2 (ral3), yeast BEM1-binding proteins BOI2 (BEB1) and BOB1 (BOI1), yeast fusion protein FUS1, yeast protein RSV167, yeast protein SSU8⁹, yeast hypothetical proteins YAR014c, YFR024c, YHL002w, YHR016c, YJL020C, and YHR114w, hypothetical
5 fission yeast protein SpAC12C2.05c, and *C. elegans* hypothetical protein F42H10.3. Of these proteins, multiple SH3 domains occur in vertebrate GRB2 protein, *C. elegans* sem-5 protein, *Drosophila* DRK protein, oncoprotein Crk, mammalian neutrophil cytosolic activators of NADPH oxidase p47 and p67, yeast protein BEM1, fission yeast protein scd2, yeast hypothetical protein YHR114w, mammalian cytoplasmic protein
10 Nck, *C. elegans* neutrophil cytosolic activator of NADPH oxidase B0303.7, and yeast actin-binding protein SLA1. Of these proteins, three or more SH3 domains occur in mammalian cytoplasmic protein Nck, *C. elegans* neutrophil cytosolic activator of NADPH oxidase B0303.7, and yeast actin-binding protein SLA1. The presence of SH3 domain binding sites in INTERCEPT 217 indicates that INTERCEPT 217
15 interacts with one or more of these and other SH3 domain-containing proteins and is thus involved in physiological processes in which one or more of these or other SH3 domain-containing proteins are involved.

Human INTERCEPT 217 exhibits amino acid sequence similarity to porcine ribonuclease inhibitor, a protein which binds with high affinity to pancreatic
20 ribonucleases and inhibits their activity. INTERCEPT 217 thus is involved with similar physiological processes in humans. An alignment of the amino acid sequences of human INTERCEPT 217 and porcine ribonuclease inhibitor protein (SwissProt Accession number P10775) is shown in Figure 19G. In this alignment (made using the ALIGN software {Myers and Miller (1989) CABIOS, ver. 2.0}; pam120.mat scoring
25 matrix; gap opening penalty = 12, gap extension penalty = 4), the proteins are 20.5% identical. An alignment of human (SEQ ID NO: 273) and murine INTERCEPT 217 amino acid sequences (SEQ ID NO: 363; made using BESTFIT software, BLOSUM62 scoring matrix, gap opening penalty = 12, frameshift gap penalty = 5, gap extension penalty = 4). In this alignment, the human and murine amino acid sequences are

71.3% identical in the overlapping region. Alignment of human and murine INTERCEPT 217 ORFs indicated 79.9% nucleotide sequence identity in the overlapping region.

The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that human INTERCEPT 217 protein includes an
5 approximately 20 (i.e., 18, 19, 20, 21, or 22) amino acid residue signal peptide (amino acid residues 1 to 20 of SEQ ID NO: 273; SEQ ID NO: 274) preceding the mature INTERCEPT 217 protein (i.e., approximately amino acid residues 21 to 455 of SEQ ID NO: 273; SEQ ID NO: 275). In one embodiment, human INTERCEPT 217 protein
10 includes an extracellular domain (amino acid residues 21 to 383 of SEQ ID NO: 273; SEQ ID NO: 276); a transmembrane domain (amino acid residues 384 to 403 of SEQ ID NO: 273; SEQ ID NO: 277); and a cytoplasmic domain (amino acid residues 404 to 455 of SEQ ID NO: 273; SEQ ID NO: 278). In an alternative embodiment, human INTERCEPT 217 protein includes a cytoplasmic domain (amino acid residues 21 to
15 383 of SEQ ID NO: 273; SEQ ID NO: 276); a transmembrane domain (amino acid residues 384 to 403 of SEQ ID NO: 273; SEQ ID NO: 277); and an extracellular domain (amino acid residues 404 to 455 of SEQ ID NO: 273; SEQ ID NO: 278).

The SIGNALP program predicted that murine INTERCEPT 217 protein includes an approximately 15 (i.e., 13, 14, 15, 16, or 17) amino acid residue signal
20 peptide (amino acid residues 1 to 16 of SEQ ID NO: 363; SEQ ID NO: 364) preceding the mature INTERCEPT 217 protein (i.e., approximately amino acid residues 16 to 320 of SEQ ID NO: 363; SEQ ID NO: 365). In one embodiment, murine INTERCEPT 217 protein includes an extracellular domain (amino acid residues 16 to 213 of SEQ ID NO: 363; SEQ ID NO: 366); a transmembrane domain (amino acid residues 214 to 233
25 of SEQ ID NO: 363; SEQ ID NO: 367); and a cytoplasmic domain (amino acid residues 234 to 320 of SEQ ID NO: 363; SEQ ID NO: 368). In an alternative embodiment, murine INTERCEPT 217 protein includes a cytoplasmic domain (amino acid residues 16 to 213 of SEQ ID NO: 363; SEQ ID NO: 366); a transmembrane domain (amino acid residues 214 to 233 of SEQ ID NO: 363; SEQ ID NO: 367); and

an extracellular domain (amino acid residues 234 to 320 of SEQ ID NO: 363; SEQ ID NO: 368).

Figure 19F depicts a hydrophobicity plot of human INTERCEPT 217 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to 20 of SEQ ID NO: 273 is the signal sequence of human INTERCEPT 217 (SEQ ID NO: 274). The hydrophobic region which corresponds to amino acid residues 384 to 403 of SEQ ID NO: 273 is the transmembrane domain of human INTERCEPT 217 (SEQ ID NO: 277). As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human INTERCEPT 217 protein from about amino acid residue 355 to about amino acid residue 380 appears to be located at or near the surface of the protein, while the region from about amino acid residue 190 to about amino acid residue 210 appears not to be located at or near the surface. Figure 19L depicts a hydrophobicity plot of murine INTERCEPT 217 protein.

The predicted molecular weight of human INTERCEPT 217 protein without modification and prior to cleavage of the signal sequence is about 49.8 kilodaltons. The predicted molecular weight of the mature human INTERCEPT 217 protein without modification and after cleavage of the signal sequence is about 47.4 kilodaltons.

The predicted molecular weight of murine INTERCEPT 217 protein, without modification and prior to cleavage of the signal sequence is about 35.5 kilodaltons. The predicted molecular weight of the mature human INTERCEPT 217 protein without modification and after cleavage of the signal sequence is about 33.8 kilodaltons.

Northern analysis experiments indicated that mRNA corresponding to the cDNA encoding INTERCEPT 217 is expressed in two forms, one having an apparent approximate size of about 6 kilobases and another having an apparent approximate size of about 3 kilobases (i.e., corresponding to the size of the INTERCEPT 217 cDNA). These experiments indicated that INTERCEPT 217 is expressed in the tissues listed in

Table XVII, wherein "++" indicates strong expression, "+" indicates lower expression, and "+/-" indicates still lower expression.

Table XVII

Animal	Tissue	Relative Level of Expression
Human	pancreas	++
	skeletal muscle	+
	heart	+/-
	brain	+/-
	placenta	+/-
	lung	+/-
	liver	+/-
	kidney	+/-

- 5 An assay to detect possible secretion of INTERCEPT 217 protein was negative. This assay was performed as described elsewhere in this disclosure.

Uses of INTERCEPT 217 Nucleic acids,
Polypeptides, and Modulators Thereof

- 10 INTERCEPT 217 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not expressed. Based on the observation that INTERCEPT 217 is expressed in pancreas, skeletal muscle, heart, brain, placenta, lung, liver, and kidney tissue, INTERCEPT 217 protein is involved in one or more biological processes which occur in these tissues. In particular, INTERCEPT 217 is involved in modulating binding of cells of one or more of these tissues with proteins of other cells or with secreted proteins which occur in the extracellular environment of one or more of these tissues. INTERCEPT 217 is especially implicated in disorders of skeletal muscle (e.g., protection of skeletal muscle
- 15

cells during ischemia and in bruised tissue), and more especially those involving the pancreas (e.g., diabetes, pancreatitis, and the like).

Structural similarity of human INTERCEPT 217 protein with human GP-IB α indicates that INTERCEPT 217 is involved in binding extracellular proteins and other
5 ligands. INTERCEPT 217 protein is involved in binding of proteins which induce release of pancreatic digestive enzymes (e.g., amylases, lipases, proteases, and nucleases) from pancreatic cells, and in disorders associated with insufficient or inappropriate release of such enzymes. INTERCEPT 217 protein is also involved in binding of secreted pancreatic digestive enzymes in pancreatic tissue, thereby
10 protecting pancreatic tissue from autodigestion. Thus, INTERCEPT 217 protein is involved in disorders such as diabetes, pancreatitis, and pancreatic carcinoma which involve acute and chronic autodigestive damage to pancreatic tissues. Homology of INTERCEPT 217 protein with porcine ribonuclease inhibitor protein is a further indication of this involvement.

15 The presence of LRR domains in human INTERCEPT 217 protein and detection of its expression in a variety of tissues indicate that the tissue protective functions of INTERCEPT 217 are not limited to pancreatic tissues, but are involved in protection of other tissues as well (e.g., skeletal muscle, heart, brain, placenta, lung, liver, prostate, and kidney tissues). INTERCEPT 217 is therefore involved in
20 protection of these (and likely other tissues) from the effects of inflammation, autoimmunity, infection, and acute and chronic traumas.

Presence in INTERCEPT 217 protein of multiple SH3 domain binding sites indicates that INTERCEPT 217 protein interacts with one or more SH3 domain-containing proteins. Thus, INTERCEPT 217 protein mediates binding of proteins (i.e.,
25 binding of proteins to INTERCEPT 217 and to one another to form protein complexes) in cells in which it is expressed. INTERCEPT 217 is also involved in transduction of signals between the exterior environment of cells (i.e., including from other cells) and the interior of cells in which it is expressed. INTERCEPT 217 mediates regulation of cell growth and proliferation, endocytosis, activation of respiratory burst, and other

physiological processes triggered by transmission of a signal via a protein with which INTERCEPT 217 interacts.

INTERCEPT 217-related molecules can be used to modulate one or more of the activities in which INTERCEPT 217 is involved and can also be used to prevent,
5 diagnose, or treat one or more of the disorders in which INTERCEPT 217 is involved.

INTERCEPT 217 polypeptides, nucleic acids, and modulators thereof, can, for example, be used to treat pancreatic disorders, such as the pancreatic disorders described elsewhere in this disclosure. INTERCEPT 217 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or
10 alleviate one or more of these disorders.

In another example, INTERCEPT 217 polypeptides, nucleic acids, and modulators thereof, can be used to treat disorders of skeletal muscle, such as the skeletal muscle disorders described elsewhere in this disclosure. INTERCEPT 217 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate,
15 diagnose, inhibit, prevent, or alleviate one or more of these disorders.

Because INTERCEPT 217 exhibits expression in heart tissue, INTERCEPT 217 nucleic acids, proteins, and modulators thereof can be used to treat disorders such as the cardiovascular disorders described elsewhere in this disclosure. INTERCEPT 217 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate,
20 diagnose, inhibit, prevent, or alleviate one or more of these disorders.

In another example, INTERCEPT 217 polypeptides, nucleic acids, and modulators thereof, can be used to treat disorders of the brain, such as the brain disorders described elsewhere in this disclosure. INTERCEPT 217 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit,
25 prevent, or alleviate one or more of these disorders.

In another example, INTERCEPT 217 polypeptides, nucleic acids, and modulators thereof, can be used to treat placental disorders, such as toxemia of pregnancy (e.g., preeclampsia and eclampsia), placentitis, and spontaneous abortion.

INTERCEPT 217 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

In another example, INTERCEPT 217 polypeptides, nucleic acids, and modulators thereof, can be used to treat pulmonary (i.e., lung) disorders, such as
5 atelectasis, cystic fibrosis, rheumatoid lung disease, pulmonary congestion, pulmonary edema, chronic obstructive airway disease (e.g., emphysema, chronic bronchitis, bronchial asthma, and bronchiectasis), diffuse interstitial diseases (e.g., sarcoidosis, pneumoconiosis, hypersensitivity pneumonitis, Goodpasture's syndrome, idiopathic pulmonary hemosiderosis, pulmonary alveolar proteinosis, desquamative interstitial
10 pneumonitis, chronic interstitial pneumonia, fibrosing alveolitis, hamman-rich syndrome, pulmonary eosinophilia, diffuse interstitial fibrosis, Wegener's granulomatosis, lymphomatoid granulomatosis, and lipid pneumonia), and tumors (e.g., bronchogenic carcinoma, bronchioloalveolar carcinoma, bronchial carcinoid, hamartoma, and mesenchymal tumors). INTERCEPT 217 polypeptides, nucleic acids,
15 and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

In yet another example, INTERCEPT 217 polypeptides, nucleic acids, and modulators thereof, can be used to treat hepatic (i.e., liver) disorders, such as the liver disorders described elsewhere in this disclosure. INTERCEPT 217 polypeptides,
20 nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

In still another example, INTERCEPT 217 polypeptides, nucleic acids, and modulators thereof, can be used to treat renal (i.e., kidney) disorders, such as the kidney disorders described elsewhere in this disclosure. INTERCEPT 217
25 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

INTERCEPT 297

A cDNA clone (designated jthsa085g01) encoding at least a portion of human INTERCEPT 297 protein was isolated from a human fetal spleen cDNA library. The human INTERCEPT 297 protein is predicted by structural analysis to be a
5 transmembrane protein.

The full length of the cDNA encoding human INTERCEPT 297 protein (Figure 20; SEQ ID NO: 279) is 1518 nucleotide residues. The ORF of this cDNA, nucleotide residues 40 to 1152 of SEQ ID NO: 279 (i.e., SEQ ID NO: 280), encodes a 371-amino acid transmembrane protein (Figure 20; SEQ ID NO: 281).

10 The invention thus includes purified human INTERCEPT 297 protein, both in the form of a 371 amino acid residue protein (SEQ ID NO: 281) in which the 'signal sequence' (i.e., the portion of INTERCEPT 297 protein corresponding to amino acid residues 1 to 18) described in this section is not cleaved and in the form of a 353 amino acid residue protein (SEQ ID NO: 283) in which the 'signal sequence' is cleaved.
15 Human INTERCEPT 297 protein can exist with or without the signal sequence polypeptide at the amino terminus thereof. It is likely that the 'signal sequence' is not cleaved, but is instead a transmembrane domain of the protein.

The invention includes nucleic acid molecules which encode an INTERCEPT 297 polypeptide of the invention. Such nucleic acids include, for example, a DNA
20 molecule having the nucleotide sequence listed in SEQ ID NO: 279 or some portion thereof, such as the portion which encodes mature INTERCEPT 297 protein, immature INTERCEPT 297 protein, or a domain of INTERCEPT 297 protein. These nucleic acids are collectively referred to as INTERCEPT 297 nucleic acids of the invention.

INTERCEPT 297 proteins and nucleic acid molecules encoding them comprise
25 a family of molecules having certain conserved structural and functional features.

A common domain present in INTERCEPT 297 proteins is a signal sequence. In one embodiment, a INTERCEPT 297 protein contains a signal sequence corresponding to about amino acid residues 1 to 18 of SEQ ID NO: 281 (SEQ ID NO: 282). The signal sequence can be cleaved during processing of the mature protein, but

it is likely that amino acid residues 1 to 18 of SEQ ID NO: 281 represent a (non-cleaved) transmembrane region of the protein.

INTERCEPT 297 proteins can include one or more extracellular domains. In one embodiment of the human INTERCEPT 297 protein, extracellular domains are
5 located from about amino acid residues 19 to 47, from about amino acid residues 110 to 118, from about amino acid residues 162 to 175, from about amino acid residues 234 to 260, and from about amino acid residues 313 to 319 of SEQ ID NO: 281 (SEQ ID NOs: 284-288, respectively). In an alternative embodiment, extracellular domains are located from about amino acid residue 69 to 88, from about amino acid residue 138 to
10 144, from about amino acid residue 193 to 215, from about amino acid residue 284 to 292, and from about amino acid residue 337 to 371 of SEQ ID NO: 281 (SEQ ID NOs: 298-302, respectively).

In addition, INTERCEPT 297 includes one or more transmembrane domains. In one embodiment, a INTERCEPT 297 protein of the invention contains
15 transmembrane domains corresponding to about amino acid residues 48 to 68, about amino acid residues 89 to 109, about amino acid residues 119 to 137, about amino acid residues 145 to 161, about amino acid residues 176 to 192, about amino acid residues 216 to 233, about amino acid residues 261 to 283, about amino acid residues 293 to 312, and about amino acid residues 320 to 336 of SEQ ID NO: 281 (SEQ ID NOs:
20 289-297, respectively). As indicated above, it is likely that the 'signal sequence' of INTERCEPT 297 is an additional (and non-cleaved) transmembrane region.

The present invention includes INTERCEPT 297 proteins having one or more cytoplasmic domains. In one embodiment of the human INTERCEPT 297 protein, cytoplasmic domains are located from about amino acid residue 69 to 88, from about
25 amino acid residue 138 to 144, from about amino acid residue 193 to 215, from about amino acid residue 284 to 292, and from about amino acid residue 337 to 371 of SEQ ID NO: 281 (SEQ ID NOs: 298-302, respectively). In an alternative embodiment, cytoplasmic domains are located from about amino acid residues 19 to 47, from about amino acid residues 110 to 118, from about amino acid residues 162 to 175, from about

amino acid residues 234 to 260, and from about amino acid residues 313 to 319 of SEQ ID NO: 281 (SEQ ID NOs: 284-288, respectively).

INTERCEPT 297 proteins typically comprise a variety of potential post-translational modification sites (often within an extracellular domain), such as those described herein in Table XVIII, as predicted by computerized sequence analysis of INTERCEPT 297 proteins using amino acid sequence comparison software (comparing the amino acid sequence of INTERCEPT 297 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}). In certain embodiments, a protein of the invention has at least 1, 2, 4, 6, 10, 15, or 20 or more of the post-translational modification sites listed in Table XVIII.

Table XVIII

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 281	Amino Acid Sequence
N-glycosylation site	110 to 113	NMTS
	269 to 272	NISS
Protein kinase C phosphorylation site	24 to 26	SAK
	290 to 292	TTR
	297 to 299	SLR
Casein kinase II phosphorylation site	78 to 81	SSVD
	165 to 168	SKHD
	245 to 248	TLED

	74 to 79	GQSDSS
	147 to 152	GILATI
	236 to 241	GSFSGN
	268 to 273	GNISSI
	280 to 285	GISVTK
Amidation site	136 to 139	LGRR
DUF6 domain	44 to 171	See Fig. 20

Among the domains that occur in INTERCEPT 297 protein is a DUF6 domain.

- 5 In one embodiment, the protein of the invention has at least one domain that is at least 55%, preferably at least about 65%, more preferably at least about 75%, yet more preferably at least about 85%, and most preferably at least about 95% identical to this DUF6 domain.

- 10 The DUF6 domain is a transmembrane domain that is highly conserved among eukaryote, prokaryote, and archae kingdoms. This high degree of domain sequence conservation indicates that proteins of the class which includes INTERCEPT 297 are involved in fundamental membrane physiology of living cells. INTERCEPT 297 protein is therefore involved in disorders which are associated with aberrant membrane function including, for example, disorders involving abnormal membrane fluidity,
- 15 disorders involving aberrant transmembrane transport, disorders involving abnormal membrane organization, disorders involving abnormal membrane synthesis, disorders involving aberrant cell division, and the like.

The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that human INTERCEPT 297 protein includes an

approximately 18 (i.e., 16, 17, 18, 19, or 20) amino acid residue signal peptide (amino acid residues 1 to 18 of SEQ ID NO: 281; SEQ ID NO: 282) preceding the mature INTERCEPT 297 protein (i.e., approximately amino acid residues 19 to 371 of SEQ ID NO: 281; SEQ ID NO: 283). In one embodiment, human INTERCEPT 297 protein
5 includes about five extracellular domains (amino acid residues 19 to 47, 110 to 118, 162 to 175, 234 to 260, and 313 to 319 of SEQ ID NO: 281); about nine transmembrane domains (amino acid residues 48 to 68, 89 to 109, 119 to 137, 145 to 161, 176 to 192, 216 to 233, 261 to 283, 293 to 312, and 320 to 326 of SEQ ID NO: 281); and about five cytoplasmic domains (amino acid residues 69 to 88, 138 to 144,
10 193 to 215, 284 to 292, and 337 to 371 of SEQ ID NO: 281). In an alternative embodiment, human INTERCEPT 297 protein includes about five cytoplasmic domains (amino acid residues 19 to 47, 110 to 118, 162 to 175, 234 to 260, and 313 to 319 of SEQ ID NO: 281); about nine transmembrane domains (amino acid residues 48 to 68, 89 to 109, 119 to 137, 145 to 161, 176 to 192, 216 to 233, 261 to 283, 293 to
15 312, and 320 to 326 of SEQ ID NO: 281); and about five extracellular domains (amino acid residues 69 to 88, 138 to 144, 193 to 215, 284 to 292, and 337 to 371 of SEQ ID NO: 281).

Figure 20D depicts a hydrophobicity plot of human INTERCEPT 297 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively
20 hydrophilic regions are below the dashed horizontal line. Hydrophobic region corresponding to the signal sequence and the transmembrane domains are observed in this figure. As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the
25 region of human INTERCEPT 297 protein from about amino acid residue 165 to about amino acid residue 175 appears to be located at or near the surface of the protein.

The predicted molecular weight of human INTERCEPT 297 protein without modification and prior to cleavage of the signal sequence is about 40.2 kilodaltons.

The predicted molecular weight of the mature human INTERCEPT 297 protein without modification and after cleavage of the signal sequence is about 38.2 kilodaltons.

Uses of INTERCEPT 297 Nucleic acids,
5 Polypeptides, and Modulators Thereof

INTERCEPT 297 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not expressed. Based on the observation that INTERCEPT 297 is expressed in human fetal spleen, INTERCEPT 297 protein is involved in one or more biological processes which
10 occur in fetal and spleen tissues. In particular, INTERCEPT 297 is involved in modulating growth, proliferation, survival, differentiation, and activity of cells including, but not limited to, spleen and fetal cells of the animal in which it is normally expressed. Thus, INTERCEPT 297 has a role in disorders which affect these cells and their growth, proliferation, survival, differentiation, and activity (e.g., hematologic and
15 immune disorders). Expression of INTERCEPT 297 in an animal is also involved in modulating growth, proliferation, survival, differentiation, and activity of cells and viruses which are foreign to the host (i.e., bacterial, fungal, and viral infections).

INTERCEPT 297 bears amino acid sequence similarity to *Caenorhabditis elegans* protein C2G12.12, and therefore exhibits one or more activities analogous to
20 that protein.

INTERCEPT 297 nucleic acids, proteins, and modulators thereof can be used to modulate proliferation, migration, morphology, differentiation, function, or some combination of these, of cells that form the spleen, (e.g., cells of the splenic connective tissue, splenic smooth muscle cells, or endothelial cells of the splenic blood vessels) or
25 of blood cells that are processed (e.g., regenerated, matured, or phagocytized) within the spleen, as described elsewhere in this disclosure. INTERCEPT 297 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

Structural analysis of INTERCEPT 297 and the presence of a DUF6 domain therein indicate that INTERCEPT 297 is involved in disorders which affect membrane structure and function. INTERCEPT 297 can be used to affect development and persistence of disorders involving inappropriate membrane structure and function, such as atherogenesis, arteriosclerosis, and various transmembrane transport disorders. Other examples of disorders for which INTERCEPT 297 is useful include disorders involving generation and persistence of an immune response to bacterial, fungal, and viral infections. INTERCEPT 297 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

The structure of INTERCEPT 297 is analogous to the structures of integral membrane proteins responsible for transmembrane transport of molecules such as sugars, ions, and the like. INTERCEPT 297 is thus involved in one or more transmembrane transport-related disorders such as cystic fibrosis, nerve conduction disorders (e.g., pain and loss or failure of sensation), muscle contraction disorders (e.g., cardiac insufficiency), metal ion uptake disorders (e.g., hemochromatosis), and the like. INTERCEPT 297 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

TANGO 276

A cDNA clone (designated jthsa006e01) encoding at least a portion of human TANGO 276 protein was isolated from a human fetal spleen cDNA library. The human TANGO 276 protein is predicted by structural analysis to be a secreted protein.

The full length of the cDNA encoding human TANGO 276 protein (Figure 21; SEQ ID NO: 303) is 2811 nucleotide residues. The ORF of this cDNA, nucleotide residues 58 to 786 of SEQ ID NO: 303 (i.e., SEQ ID NO: 304), encodes a 243-amino acid secreted protein (Figure 21; SEQ ID NO: 305).

The invention thus includes purified human TANGO 276 protein, both in the form of the immature 243 amino acid residue protein (SEQ ID NO: 305) and in the

form of the mature, approximately 223 amino acid residue protein (SEQ ID NO: 307). Mature human TANGO 276 protein can be synthesized without the signal sequence polypeptide at the amino terminus thereof, or it can be synthesized by generating immature TANGO 276 protein and cleaving the signal sequence therefrom.

5 The invention includes nucleic acid molecules which encode a TANGO 276 polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the nucleotide sequence listed in SEQ ID NO: 303 or some portion thereof, such as the portion which encodes mature TANGO 276 protein, immature TANGO 276 protein, or a domain of TANGO 276 protein. These nucleic acids are
10 collectively referred to as TANGO 276 nucleic acids of the invention.

 TANGO 276 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional features, as indicated by the conservation of amino acid sequence between human TANGO 276 protein and the murine protein designated M-Sema-F (see Inagaki et al. (1995) FEBS
15 Lett. 370:269-272), as shown in Figures 21F to 21H.

 A common domain present in TANGO 276 proteins is a signal sequence. In one embodiment, a TANGO 276 protein contains a signal sequence corresponding to about amino acid residues 1 to 20 of SEQ ID NO: 305 (SEQ ID NO: 306). The signal sequence is cleaved during processing of the mature protein.

20 TANGO 276 proteins can exist in a secreted form, such as a mature protein having the amino acid sequence of amino acid residues 21 to 243 of SEQ ID NO: 305 (SEQ ID NO: 307).

 TANGO 276 proteins typically comprise a variety of potential post-translational modification sites (often within an extracellular domain), such as those
25 described herein in Table XIX, as predicted by computerized sequence analysis of TANGO 276 proteins using amino acid sequence comparison software (comparing the amino acid sequence of TANGO 276 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}). In

certain embodiments, a protein of the invention has at least 1, 2, 4, 6, or all 8 of the post-translational modification sites listed in Table XIX.

Table XIX

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 305	Amino Acid Sequence
N-glycosylation site	106 to 109	NQTE
	121 to 124	NASH
cAMP- or cGMP-dependent protein kinase phosphorylation site	43 to 46	RRFS
Protein kinase C phosphorylation site	194 to 196	SLK
Casein kinase II phosphorylation site	34 to 37	SSGE
	57 to 60	TLTE
N-myristoylation site	16 to 21	GLGIGA
	68 to 73	GAREAL
Sema domain	53 to 141	See Fig. 21

5 A Sema domain occurs in human TANGO 276 protein. In one embodiment, the protein of the invention has at least one domain that is at least 55%, preferably at least about 65%, more preferably at least about 75%, yet more preferably at least about 85%, and most preferably at least about 95% identical to this Sema domain.

10 Sema domains occur in semaphorin proteins. Semaphorins are a large family of secreted and transmembrane proteins, some of which function as repellent signals during neural axon guidance. The Sema domain and a variety of semaphorin proteins in which it occurs are described, for example, in Winberg et al. (1998 Cell 95:903-916). Sema domains also occur in human hepatocyte growth factor receptor (SwissProt Accession no. P08581) and the similar neuronal and epithelial

15 transmembrane receptor protein (SwissProt Accession no. P51805). The presence of a Sema domain in human TANGO 276 protein indicates that TANGO 276 is involved in

one or more physiological processes in which the semaphorins are involved, has biological activity in common with one or more of the semaphorins, or both.

Human TANGO 276 protein exhibits considerable sequence similarity to murine M-Sema F protein (GenBank Accession no. S79463), as indicated herein in
5 Figures 21F to 21H. Figures 21F to 21H depict an alignment of the amino acid sequences of human TANGO 276 protein (SEQ ID NO: 305) and murine M-Sema F protein (SEQ ID NO: 335). In this alignment (pam120.mat scoring matrix, gap opening penalty = 12, gap extension penalty = 4), the amino acid sequences of the proteins are 76.1% identical. Figures 21I through 21R depict an alignment of the
10 nucleotide sequences of cDNA encoding human TANGO 276 protein (SEQ ID NOs: 303) and murine cDNA encoding M-Sema F protein (SEQ ID NO: 336). In this alignment (pam120.mat scoring matrix, gap opening penalty = 12, gap extension penalty = 4), the nucleic acid sequences of the cDNAs are 79.7% identical. Thus, TANGO 276 is related to murine M-Sema F and shares functional similarities to that
15 protein.

It is known that semaphorins are bi-functional, capable of functioning either as attractive axonal guidance proteins or as repellent axonal guidance proteins (Wong et al. (1997) Development 124:3597-3607). Furthermore, semaphorins bind with neuronal cell surface proteins designated plexins, which are expressed on both neuronal
20 cells and cells of the immune system (Comeau et al. (1998) Immunity 8:473-482; Jin and Strittmatter (1997) J. Neurosci. 17:6256-6263).

The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that human TANGO 276 protein includes an approximately 20 (i.e., 18, 19, 20, 21, or 22) amino acid signal peptide (amino acid
25 residues 1 to 20 of SEQ ID NO: 305; SEQ ID NO: 306) preceding the mature TANGO 276 protein (i.e., approximately amino acid residues 21 to 243 of SEQ ID NO: 304; SEQ ID NO: 307). Human TANGO 276 protein is a secreted protein.

Figure 21E depicts a hydrophobicity plot of human TANGO 276 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively

hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to about amino acid residues 1 to 20 of SEQ ID NO: 305 is the signal sequence of human TANGO 276. As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human TANGO 276 protein from about amino acid residue 90 to about amino acid residue 105 appears to be located at or near the surface of the protein, while the region from about amino acid residue 170 to about amino acid residue 180 appears not to be located at or near the surface.

The predicted molecular weight of human TANGO 276 protein without modification and prior to cleavage of the signal sequence is about 27.1 kilodaltons. The predicted molecular weight of the mature human TANGO 276 protein without modification and after cleavage of the signal sequence is about 24.8 kilodaltons.

Northern analysis experiments indicated that mRNA corresponding to the cDNA encoding TANGO 276 is expressed in the tissues listed in Table XX, wherein "++" indicates a greater level of expression and "+" indicates a lower level of expression.

Table XX

Animal	Tissue	Relative Level of Expression
Human	heart	++
	placenta	++
	brain	+
	lung	+
	liver	+
	skin	+
	kidney	+
	pancreas	+

Uses of TANGO 276 Nucleic acids,
Polypeptides, and Modulators Thereof

TANGO 276 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not expressed. Based on the observation that TANGO 276 is expressed in human heart and placenta tissues, to a lesser extent in brain, lung, liver, skin, kidney, and pancreas tissues, and in fetal spleen tissue, TANGO 276 protein is involved in one or more biological processes which occur in these tissues. In particular, TANGO 276 is involved in modulating growth, proliferation, survival, differentiation, and activity of cells including, but not limited to, heart, placenta, spleen, brain, lung, liver, skin, kidney, and pancreas cells of the animal in which it is normally expressed. Thus, TANGO 276 has a role in disorders which affect these cells and their growth, proliferation, survival, differentiation, and activity.

Because TANGO 276 exhibits expression in the heart, TANGO 276 nucleic acids, proteins, and modulators thereof can be used to treat cardiovascular disorders, such as those described elsewhere in this disclosure. TANGO 276 polypeptides, nucleic acids, or modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

In another example, TANGO 276 polypeptides, nucleic acids, and modulators thereof can be used to treat placental disorders, such as those described elsewhere in this disclosure. TANGO 276 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

In another example, TANGO 276 polypeptides, nucleic acids, or modulators thereof, can be used to treat disorders of the brain, such as the brain disorders described elsewhere in this disclosure. TANGO 276 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

TANGO 276 polypeptides, nucleic acids, and modulators thereof can be associated with pulmonary (i.e., lung) disorders, such as the pulmonary disorders described elsewhere in this disclosure. TANGO 276 polypeptides, nucleic acids, or modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate
5 one or more of these disorders.

In another example, TANGO 276 polypeptides, nucleic acids, and modulators thereof, can be used to treat hepatic (i.e., liver) disorders, such as the liver disorders described elsewhere in this disclosure. TANGO 276 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate
10 one or more of these disorders.

Examples of skin disorders with which TANGO 276 can be associated include those described elsewhere in this disclosure. TANGO 276 proteins, nucleic acids encoding them, and agents that modulate activity or expression of either of these can be used to prognosticate, diagnose, treat, and inhibit one or more of these disorders.

15 In another example, TANGO 276 polypeptides, nucleic acids, or modulators thereof, can be used to treat renal (i.e., kidney) disorders, such as the kidney disorders described elsewhere in this disclosure. TANGO 276 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

20 Pancreatic disorders in which TANGO 276 can be involved include the pancreatic disorders described elsewhere in this disclosure. TANGO 276 polypeptides, nucleic acids, or modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

The presence of the Sema domain in TANGO 276 indicates that this protein is
25 involved in development of neuronal and epithelial tissues and also functions as a repellent protein which guides axonal development. TANGO 276 modulates nerve growth and regeneration and also modulates growth and regeneration of other epithelial tissues. TANGO 276 is thus involved in a variety of neuronal disorder including, but not limited to, one or more of seizure, epilepsy, (regeneration of) neuronal damage,

pain (including, for example, migraine, headache, and other chronic pain), infections of the central nervous system, multiple sclerosis, sleep disorders, psychological disorders, nerve root disorders, and the like. Presence of a Sema domain in TANGO 276 further indicates that TANGO 276 has one or more physiological roles in common with other
5 proteins (e.g., secreted and transmembrane semaphorins, collapsins, neuropilins, plexins, and the like) in which the Sema domain occurs. Thus, TANGO 276 is implicated in development, maintenance, and regeneration of neuronal connections and networks, in modulating differentiation of cells of the immune system, in modulating cytokine production by cells of the immune system, in modulating reactivity of cells of
10 the immune system toward cytokines, in modulating initiation and persistence of an inflammatory response, and in modulating proliferation of epithelial cells. Sema domain-containing proteins have also been implicated in development and progression of small cell lung cancer, in normal brain development, and immune system regulation. This indicates that TANGO 276 is also involved in one or more of these processes and
15 in disorders relating to these processes (e.g., small cell lung cancer, brain development disorders, and immune and auto-immune disorders). TANGO 276 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

The observation that TANGO 276 shares identity with the murine semaphorin
20 protein designated M-Sema F suggests that TANGO 276 has activity identical or analogous to the activity of this protein. These observations indicate that TANGO 276 modulates growth, proliferation, survival, differentiation, and activity of neuronal cells. Thus, TANGO 276 protein is useful, for example, for modulating and guiding neural axon development and for modulating establishment and maintenance of neuronal
25 networks.

TANGO 292

A cDNA clone (designated jthkf040b11) encoding at least a portion of human TANGO 292 protein was isolated from a human normal embryonic keratinocyte cDNA library. A corresponding gerbil cDNA clone (designated jtiba040e12) was also
5 isolated, and encoded at least a portion of gerbil TANGO 292 protein. The human and TANGO 292 proteins are predicted by structural analysis to be transmembrane proteins.

The full length of the cDNA encoding human TANGO 292 protein (Figure 22; SEQ ID NO: 308) is 2498 nucleotide residues. The ORF of this cDNA, nucleotide
10 residues 205 to 882 of SEQ ID NO: 308 (i.e., SEQ ID NO: 309), encodes a 226-amino acid residue transmembrane protein (Figure 22; SEQ ID NO: 310). The full length of the cDNA encoding gerbil TANGO 292 protein (Figure 22; SEQ ID NO: 351) is 2002 nucleotide residues. The ORF of this cDNA, nucleotide residues 89 to 763 of SEQ ID NO: 351 (i.e., SEQ ID NO: 352), encodes a 225-amino acid transmembrane protein
15 (Figure 22; SEQ ID NO: 353).

The invention thus includes purified human TANGO 292 protein, both in the form of the immature 226 amino acid residue protein (SEQ ID NO: 310) and in the form of the mature, approximately 209 amino acid residue protein (SEQ ID NO: 312). The invention also includes purified gerbil TANGO 292 protein, both in the form of
20 the immature 225-amino acid residue (SEQ ID NO: 353) protein and in the form of the mature, approximately 208-amino acid residue protein (SEQ ID NO: 355). Mature human or gerbil TANGO 292 protein can be synthesized without the signal sequence polypeptide at the amino terminus thereof, or it can be synthesized by generating immature TANGO 292 protein and cleaving the signal sequence therefrom.

25 The invention includes nucleic acid molecules which encode a TANGO 292 polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the nucleotide sequence listed in SEQ ID NO: 308 or 351 or some portion thereof, such as the portion which encodes mature human or gerbil TANGO 292 protein, immature human or gerbil TANGO 292 protein, or a domain of human or

gerbil TANGO 292 protein. These nucleic acids are collectively referred to as TANGO 292 nucleic acids of the invention.

TANGO 292 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional features. This family includes, for example, human and gerbil TANGO 292 proteins and nucleic acid molecules described herein.

A common domain present in TANGO 292 proteins is a signal sequence. In one embodiment, a TANGO 292 protein contains a signal sequence corresponding to about amino acid residues 1 to 17 of SEQ ID NO: 310 (SEQ ID NO: 311) or to about amino acid residues 1 to 17 of SEQ ID NO: 353 (SEQ ID NO: 354). The signal sequence is cleaved during processing of the mature protein.

TANGO 292 proteins can include an extracellular domain. The human TANGO 292 protein extracellular domain is located from about amino acid residue 18 to about amino acid residue 113 of SEQ ID NO: 310 (SEQ ID NO: 313). The gerbil TANGO 292 protein extracellular domain includes at least about amino acid residues 18 to 112 of SEQ ID NO: 353 (SEQ ID NO: 356).

In addition, TANGO 292 include a transmembrane domain. In one embodiment, a human TANGO 292 protein contains a transmembrane domain corresponding to about amino acid residues 114 to 138 of SEQ ID NO: 310 (SEQ ID NO: 314). Gerbil TANGO 292 protein includes a transmembrane domain corresponding to about amino acid residues 113 to 137 of SEQ ID NO: 353 (SEQ ID NO: 357).

The present invention includes TANGO 292 proteins having a cytoplasmic domain, particularly including proteins having a carboxyl-terminal cytoplasmic domain. The human TANGO 292 cytoplasmic domain is located from about amino acid residue 139 to amino acid residue 226 of SEQ ID NO: 310 (SEQ ID NO: 315). The gerbil TANGO 292 cytoplasmic domain is located from about amino acid residue 138 to amino acid residue 225 of SEQ ID NO: 353 (SEQ ID NO: 358).

TANGO 292 proteins typically comprise a variety of potential post-translational modification sites (often within an extracellular domain), such as those described herein in Table XXIa as predicted by computerized sequence analysis of human TANGO 292 protein, or in Table XXIb as predicted by computerized sequence analysis of gerbil TANGO 292 protein, using amino acid sequence comparison software (comparing the amino acid sequence of TANGO 292 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}). In certain embodiments, a protein of the invention has at least 1, 2, 4, 6, or all of the post-translational modification sites listed in Table XXIa or in Table XXIb.

Table XXIa

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 310	Amino Acid Sequence
cAMP- or cGMP-dependent protein kinase phosphorylation site	197 to 200	RKHS
Protein kinase C phosphorylation site	37 to 39 97 to 99 102 to 104 196 to 198	TSK SAK TTK TRK
Casein kinase II phosphorylation site	37 to 40 103 to 106 180 to 183	TSKE TKSD SVED
N-myristoylation site	116 to 121	GLLTGL
Vitamin K-dependent carboxylation domain	56 to 98	See Fig. 22

Table XXIb

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 353	Amino Acid Sequence
cAMP- or cGMP-dependent protein kinase phosphorylation site	196 to 199	RKHS
Protein kinase C phosphorylation site	23 to 25	SLK
	37 to 39	SKK
	96 to 98	SVK
	101 to 103	TTR
	155 to 157	TRR
	195 to 197	TRK
Casein kinase II phosphorylation site	74 to 77	SYEE
	102 to 105	TRSD
	155 to 157	THEE
	195 to 197	SSSE
N-myristoylation site	33 to 38	GVFASK
	115 to 120	GLLTGL
Vitamin K-dependent carboxylation domain	55 to 92	See Fig. 22

Among the domains that occur in TANGO 292 protein is a vitamin K-
dependent carboxylation domain. In one embodiment, the protein of the invention has
5 at least one domain that is at least 55%, preferably at least about 65%, more preferably
at least about 75%, yet more preferably at least about 85%, and most preferably at least
about 95% identical to this vitamin K-dependent carboxylation domain.

The vitamin K-dependent carboxylation domain has the following consensus
sequence (SEQ ID NO: 454), wherein standard single-letter amino acid codes are used
10 and 'X' refers to any amino acid residue.

-X₁₂-E-X₃-E-X-C-X₆-(D or E or N)-X-(L or I or V or M or F or Y)-X₉-(F or Y or W)-
Glutamic acid residues within this consensus region are potential vitamin K-dependent
carboxylation sites. Human TANGO 292 has 9 glutamic acid residues in the vitamin
K-dependent carboxylation domain located from about amino acid residue 56 to 98 of
5 SEQ ID NO: 310, namely at amino acid residues 58, 66, 68, 71, 72, 77, 78, 81, and 86
of SEQ ID NO: 310, and gerbil TANGO 292 has 10 glutamic acid residues in the
vitamin K-dependent carboxylation domain located from about amino acid residue 55
to 92 of SEQ ID NO: 353, namely at amino acid residues 57, 65, 67, 70, 71, 76, 77, 80,
86, and 87 of SEQ ID NO: 353. In one embodiment, the protein of the invention is
10 carboxylated at one or more of these glutamic acid residues. In some proteins in which
a vitamin K-dependent carboxylation domain occurs, many of the glutamic acid
residues which occur from the amino terminus of the protein through the conserved
aromatic residue at the carboxyl terminal end of the domain are carboxylated. Human
TANGO 292 has 13 glutamic acid residues in the region from the amino terminus of
15 (both the immature and mature forms of) the protein and the tryptophan residue at
amino acid residue 93 of SEQ ID NO: 310, and also has another glutamic acid residue
at position 95 of SEQ ID NO: 310 which can also be carboxylated. In addition, human
TANGO 292 protein has four sets of paired (i.e., adjacent) glutamic acid residues, at
residues 33-34, 40-41, 71-72, and 77-78 and a pair of glutamic acid residues (66 and
20 68) which are separated by a single residue. Similarly, gerbil TANGO 292 has 12
glutamic acid residues in the region from the amino terminus of (both the immature
and mature forms of) the protein and the tryptophan residue at amino acid residue 92 of
SEQ ID NO: 353, and also has another glutamic acid residue at position 94 of SEQ ID
NO: 353 which can also be carboxylated. In addition, gerbil TANGO 292 protein has
25 three sets of glutamic acid residues, at residues 70-71, 76-77, and 86-87, and a pair of
glutamic acid residues (65 and 67) which are separated by a single residue. The protein
of the invention includes proteins which are carboxylated at one or more of the
individual or paired glutamic acid residues.

TANGO 292, like other vitamin K-dependent carboxylation domain-containing proteins, is involved in binding, uptake, and response to metal cations such as calcium, to proteins, and to small molecules. Other proteins in which a vitamin K-dependent carboxylation domain occurs include, for example, osteocalcin (bone-Gla protein),
5 matrix Gla protein, various plasma proteins such as prothrombin, coagulation factors VII, IX, and X, proline rich Gla domain-containing proteins PRGP1 and PRGP2, and proteins C, S, and Z. Thus, TANGO 292 is involved in physiological processes in which one or more of these other vitamin K-dependent carboxylation domain-containing proteins is involved.

10 The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that human TANGO 292 protein includes an approximately 17 (i.e., 15, 16, 17, 18, or 19) amino acid residue signal peptide (amino acid residues 1 to 17 of SEQ ID NO: 310; SEQ ID NO: 311) preceding the mature TANGO 292 protein (i.e., approximately amino acid residues 18 to 226 of SEQ ID
15 NO: 310; SEQ ID NO: 312). In one embodiment, human TANGO 292 protein includes an extracellular domain (amino acid residues 18 to 113 of SEQ ID NO: 310; SEQ ID NO: 313); a transmembrane domain (amino acid residues 114 to 138 of SEQ ID NO: 310; SEQ ID NO: 314); and a cytoplasmic domain (amino acid residues 139 to 225 of SEQ ID NO: 310; SEQ ID NO: 315). In an alternative embodiment, human
20 TANGO 292 protein includes a cytoplasmic domain (amino acid residues 18 to 113 of SEQ ID NO: 310; SEQ ID NO: 313); a transmembrane domain (amino acid residues 114 to 138 of SEQ ID NO: 310; SEQ ID NO: 314); and an extracellular domain (amino acid residues 139 to 225 of SEQ ID NO: 310; SEQ ID NO: 315).

The SignalP program predicted that gerbil TANGO 292 protein includes an
25 approximately 17 (i.e., 15, 16, 17, 18, or 19) amino acid residue amino acid signal peptide (amino acid residues 1 to 17 of SEQ ID NO: 353; SEQ ID NO: 354) preceding the mature TANGO 292 protein (i.e., approximately amino acid residues 18 to 225 of SEQ ID NO: 353; SEQ ID NO: 355). In one embodiment, gerbil TANGO 292 protein includes an extracellular domain (amino acid residues 18 to 112 of SEQ ID NO: 353;

SEQ ID NO: 356); a transmembrane domain (amino acid residues 113 to 137 of SEQ ID NO: 353; SEQ ID NO: 357); and a cytoplasmic domain (amino acid residues 138 to 225 of SEQ ID NO: 353; SEQ ID NO: 358). In an alternative embodiment, gerbil TANGO 292 protein includes a cytoplasmic domain (amino acid residues 18 to 112 of SEQ ID NO: 353; SEQ ID NO: 356); a transmembrane domain (amino acid residues 113 to 137 of SEQ ID NO: 353; SEQ ID NO: 357); and an extracellular domain (amino acid residues 138 to 225 of SEQ ID NO: 353; SEQ ID NO: 358).

Figure 22D depicts a hydrophobicity plot of human TANGO 292 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to 17 of SEQ ID NO: 310 is the signal sequence of human TANGO 292. The hydrophobic region which corresponds to amino acid residues 114 to 138 of SEQ ID NO: 310 is the transmembrane domain of human TANGO 292. As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human TANGO 292 protein from about amino acid residue 90 to about amino acid residue 110 appears to be located at or near the surface of the protein, while the region from about amino acid residue 190 to about amino acid residue 195 appears not to be located at or near the surface.

Figure 22M depicts a hydrophobicity plot of gerbil TANGO 292 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to 17 of SEQ ID NO: 353 is the signal sequence of gerbil TANGO 292. The hydrophobic region which corresponds to amino acid residues 113 to 137 of SEQ ID NO: 353 is the transmembrane domain of gerbil TANGO 292. As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the

region of gerbil TANGO 292 protein from about amino acid residue 90 to about amino acid residue 110 appears to be located at or near the surface of the protein.

An alignment of the human (H) and gerbil (G) ORF sequences encoding TANGO 292 protein is shown in Figures 22I-22K. This alignment was made using the
5 ALIGN software {Myers and Miller (1989) CABIOS, ver. 2.0}; pam120.mat scoring matrix; gap opening penalty = 12, gap extension penalty = 4), and indicates about 64.1% identity between these two cDNA sequences. An alignment of the amino acid sequences of gerbil (G) and human (H) TANGO 292 proteins is shown in Figure 22L. In this alignment (made using the ALIGN software {Myers and Miller (1989)
10 CABIOS, ver. 2.0}; pam120.mat scoring matrix; gap opening penalty = 12, gap extension penalty = 4), the proteins are about 77.7% identical and about 80% similar.

The predicted molecular weight of human TANGO 292 protein without modification and prior to cleavage of the signal sequence is about 25.4 kilodaltons. The predicted molecular weight of the mature human TANGO 292 protein without
15 modification and after cleavage of the signal sequence is about 23.6 kilodaltons. The predicted molecular weight of gerbil TANGO 292 protein without modification and prior to cleavage of the signal sequence is about 25.4 kilodaltons. The predicted molecular weight of the mature human TANGO 292 protein without modification and after cleavage of the signal sequence is about 23.5 kilodaltons.

20 Northern analysis experiments indicated that human mRNA corresponding to the cDNA encoding TANGO 292 is expressed in the tissues listed in Table XXIc, wherein "++" indicates strong expression, "+" indicates lower expression, "+/-" indicates still lower expression, and "-" indicates that expression could not be detected in the corresponding tissue.

Table XXIIc

Animal	Tissue	Relative Level of Expression
Human	placenta	++
	liver	++
	kidney	++
	lung	+
	pancreas	+
	heart	+/-
	brain	-
	skeletal muscle	-

Uses of INTERCEPT 292 Nucleic acids,
Polypeptides, and Modulators Thereof

- 5 TANGO 292 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not expressed. Based on the observation that TANGO 292 is expressed in human embryonic keratinocytes, and in placenta, liver, kidney, lung, pancreas, and heart tissues, TANGO 292 protein is involved in one or more biological processes which
- 10 occur in these tissues. In particular, TANGO 292 is involved in modulating growth, proliferation, survival, differentiation, and activity of cells including, but not limited to, keratinocytes and cells with which keratinocytes interact in the animal in which TANGO 292 is normally expressed. TANGO 292 is also involved in modulating growth, proliferation, survival, differentiation, and activity of placenta, liver, kidney,
- 15 lung, pancreas, and heart cells. Thus, TANGO 292 has a role in disorders which affect these cells and their growth, proliferation, survival, differentiation, and activity. TANGO 292 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

In another example, TANGO 292 polypeptides, nucleic acids, and modulators thereof can be used to treat placental disorders, such as those described elsewhere in this disclosure. TANGO 292 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

In another example, TANGO 292 polypeptides, nucleic acids, and modulators thereof, can be used to treat hepatic (i.e., liver) disorders, such as the liver disorders described elsewhere in this disclosure. TANGO 292 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

In another example, TANGO 292 polypeptides, nucleic acids, or modulators thereof, can be used to treat renal (i.e., kidney) disorders, such as the kidney disorders described elsewhere in this disclosure. TANGO 292 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

TANGO 292 polypeptides, nucleic acids, and modulators thereof can be associated with pulmonary (i.e., lung) disorders, such as the lung disorders described elsewhere in this disclosure. TANGO 292 polypeptides, nucleic acids, or modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

Pancreatic disorders in which TANGO 292 can be involved include the pancreatic disorders described elsewhere in this disclosure. TANGO 292 polypeptides, nucleic acids, or modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

Because TANGO 292 exhibits expression in the heart, TANGO 292 nucleic acids, proteins, and modulators thereof can be used to treat cardiovascular disorders. Examples of cardiovascular disorders with which TANGO 292 can be involved include those described elsewhere in this disclosure. TANGO 292 polypeptides, nucleic acids,

or modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

Presence in TANGO 292 of a vitamin K-dependent carboxylation (Gla) domain indicates that TANGO 292 is involved in physiological functions identical or
5 analogous to the functions performed by other proteins having such domains. For example, like other Gla domain-containing proteins, TANGO 292 modulates binding and uptake of calcium and other metal ions by cells which express it and the response of those cells to the presence and uptake of such ions. Human matrix Gla protein, for example, is involved in Keutel syndrome, an autosomal recessive disorder
10 characterized by abnormal cartilage calcification, peripheral pulmonary stenosis, and midfacial hypoplasia (Munroe et al. (1999) Nat. Genet. 21:142-144). Other proteins containing a Gla domain include, for example, two human proline-rich Gla proteins designated PRGP1 and PRGP2, human G domain-containing protein Gas6, and several human blood coagulation factors (Kulman et al. (1997) Proc. Natl. Acad. Sci. USA
15 94:9058-9062; Mark et al., (1996) J. Biol. Chem. 271:9785-9786; Cancela et al. (1990) J. Biol. Chem. 265:15040-15048). These proteins are involved in binding of mineral ions such as calcium, phosphate, and hydroxyapatite, binding of proteins, binding of vitamins and small molecules, and mediation of blood coagulation. Thus, TANGO 292 is involved in numerous physiological processes which are influenced by levels of
20 calcium and other metal ions in body fluids or by the presence of proteins, vitamins, or small molecules. Such processes include, for example, bone uptake, maintenance, and deposition, formation, maintenance, and repair of cartilage, formation and maintenance of extracellular matrices, movement of cells through extracellular matrices, coagulation and dissolution of blood components (e.g., blood cells and proteins), and deposition of
25 materials (e.g., lipids, cells, calcium, and the like) in arterial walls. TANGO 292 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

TANGO 292 is involved in disorders which affect the tissues in which it is normally expressed and upon which it normally acts. Thus, TANGO 292 is involved

in disorders which involve aberrant binding or aberrant failure to bind of keratinocytes or similar cells with a tissue affected by the disorder. Such disorders include, by way of example and not limitation, osteoporosis, (repair of) traumatic bone injuries, rickets, osteomalacia, Paget's disease, and other bone disorders, osteoarthritis, rheumatoid
5 arthritis, ankylosing spondylitis, Keutel syndrome, and other disorders of the joints and cartilage, iron deficiency anemia, hemophilia, inappropriate blood coagulation, stroke, arteriosclerosis, atherosclerosis, aneurysm, and other disorders related to blood and blood vessels, metastasis and other disorders related to inappropriate movement of cells through extracellular matrices, and the like. TANGO 292 polypeptides, nucleic
10 acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

TANGO 331

A cDNA clone (designated jthvb042g08) encoding at least a portion of human
15 TANGO 331 protein was isolated from a human mammary epithelium cDNA library. A corresponding cDNA clone (designated jchrc045a03) was isolated from a human heart library. The human TANGO 331 protein is predicted by structural analysis to be a secreted protein.

The full length of the cDNA encoding human TANGO 331 protein (Figure 23;
20 SEQ ID NO: 324) is 1432 nucleotide residues. The ORF of this cDNA, nucleotide residues 114 to 1172 of SEQ ID NO: 324 (i.e., SEQ ID NO: 325), encodes a 353-amino acid secreted protein (Figure 23; SEQ ID NO: 326).

The invention thus includes purified human TANGO 331 protein, both in the form of the immature 353 amino acid residue protein (SEQ ID NO: 326) and in the
25 form of the mature, approximately 329 amino acid residue protein (SEQ ID NO: 328). Mature human TANGO 331 protein can be synthesized without the signal sequence polypeptide at the amino terminus thereof, or it can be synthesized by generating immature TANGO 331 protein and cleaving the signal sequence therefrom.

The invention includes nucleic acid molecules which encode a TANGO 331 polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the nucleotide sequence listed in SEQ ID NO: 324 or some portion thereof, such as the portion which encodes mature TANGO 331 protein, immature
5 TANGO 331 protein, or a domain of TANGO 331 protein. These nucleic acids are collectively referred to as TANGO 331 nucleic acids of the invention.

TANGO 331 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional features, as indicated by the conservation of amino acid sequence between human TANGO 331
10 protein and the Chinese hamster (*Cricetulus griseus*) protein designated HT and having GenBank Accession number U48852, as shown in Figure 23E, and the conservation of nucleotide sequence between the ORFs encoding human TANGO 331 protein and Chinese hamster protein HT, as shown in Figures 23F through 23J.

A common domain present in TANGO 331 proteins is a signal sequence. In
15 one embodiment, a TANGO 331 protein contains a signal sequence corresponding to about amino acid residues 1 to 24 of SEQ ID NO: 326 (SEQ ID NO: 327). The signal sequence is cleaved during processing of the mature protein.

TANGO 331 proteins can include an extracellular domain. The human
TANGO 331 protein is a secreted protein, and thus includes an 'extracellular domain'
20 consisting of the entire mature protein (i.e., approximately residues 25 to 353 of SEQ ID NO: 326; SEQ ID NO: 328).

TANGO 331 proteins typically comprise a variety of potential post-translational modification sites (often within an extracellular domain), such as those described herein in Table XXII, as predicted by computerized sequence analysis of
25 TANGO 331 proteins using amino acid sequence comparison software (comparing the amino acid sequence of TANGO 331 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}). In certain embodiments, a protein of the invention has at least 1, 2, 4, 6, 10, 15, or 20 or more of the post-translational modification sites listed in Table XXII.

Table XXII

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 326	Amino Acid Sequence

Leucine Zipper domain	94 to 115	See Fig. 23

Among the domains that occur in TANGO 331 protein are EGF domains,
5 including a laminin-like EGF domain, a TNFR/NGFR cysteine-rich domain, a
metallothionein-like domain, and a leucine zipper domain.

EGF-like domains are about 30 to 40 amino acid residues in length and
comprise several conserved cysteine residues in one of several patterns. EGF-like
domains occur in a large number of proteins including, for example, human epidermal

growth factor (EGF), murine adipocyte differentiation inhibitor, human agrin, human growth factor amphiregulin, human growth factor betacellulin, sea urchin blastula tissue patterning proteins BP10 and Span, cattle tick glycoprotein BM86, human bone morphogenic protein 1, sea urchin suBMP, Drosophila tolloid protein, Caenorhabditis elegans developmental proteins lin-12 and glp-1, C. elegans tissue patterning protein APX-1, human calcium-dependent serine proteinase, human cartilage matrix protein, human cartilage oligomeric matrix protein, human cell surface antigen 114/A10, rat cell surface glycoprotein complex transmembrane subunit ASGP-2, human coagulation associated proteins C, Z, and S, human coagulation factors VII, IX, X, and XII, human complement components C1r, C1s, C6, C7, C8 α , C8 β , and C9, human complement-activating components of Ra-reactive factor, Drosophila epithelial development protein Crumbs, sea urchin exogastrula-inducing peptides A, C, D, and X, Drosophila cadherin-related tumor suppressor protein Fat, human fetal antigen 1 (a neuroendocrine differentiation protein derived from the delta-like protein), human fibrillins 1 and 2, sea urchin fibropellins IA, IB, IC, II, and III, human extracellular matrix proteins fibulin-1 and -2, Drosophila cell determination/axon guidance protein Argos, various poxvirus growth factor-related proteins, Drosophila developmental protein Gurken, human heparin-binding EGF-like growth factor, human transforming growth factor- α , human growth factors Lin-3 and Spitz, human hepatocyte growth factor activator, human LDL and VLDL receptors, human LDL receptor-related protein, human leukocyte antigen CD97, human cell surface glycoprotein EMR1, human cell surface glycoprotein F4/80, Japanese horseshoe crab limulus clotting factor C, mammalian membrane-bound endopeptidase Meprin A α subunit, murine milk fat globule-EGF factor 8, human glial growth factors neuregulin GGF-I and GGF-II, mammalian neurexins, human neurogenic proteins Notch, Xotch, Tan-1, and Delta, C. elegans differentiation protein Lag-2, Drosophila differentiation proteins Serrate and Slit, chordate basement membrane protein Nidogen, Plasmodium ookinete 24, 25, and 28 kilodalton surface proteins, human pancreatic secretory granule membrane glycoprotein GP2, human non-

specific cell lysis protein Perforin, human proteoglycans aggrecan, versican, perlecan, brevican, and chondroitin sulfate, human endoplasmic reticulum prostaglandin G/H synthases 1 and 2, human extracellular protein S1-5, human autocrine growth factor Schwannoma-derived growth factor, human E-, P-, and L-selectins, Arabidopsis thaliana chlorophyll complex assembly protein serine/threonine-protein kinase homolog, guinea pig sperm-egg fusion proteins PH-30 α and β , murine stromal cell derived protein-1, human teratocarcinoma-derived growth factor, mammalian extracellular protein tenascin, chicken extracellular protein TEN-A, human tenascin-X, Drosophila tenascin-like proteins TEN-A and TEN-M, human protein C activator thrombomodulin, human adhesive glycoproteins thrombospondins 1, 2, 3, and 4, human thyroid peroxidases 1 and 2, human transforming growth factor β -1 binding protein, human tyrosine-protein kinase receptors Tek and Tie, human urokinase-type plasminogen activator, human tissue plasminogen activator, human uromodulin, human vitamin K-dependent anticoagulant proteins C and S (and the related human single-chain plasma glycoprotein Z), the sea urchin 63 kilodalton sperm flagellar membrane protein, chicken Nel protein, and the hypothetical C. Elegans protein T20G5.3.

Although these proteins have a variety of activities and sites of expression, a common characteristic of most of them is that they are involved in protein-to-protein binding in the extracellular space - either to a secreted protein, a component of the extracellular matrix, or to an extracellular portion of an integral membrane protein. Based on this shared characteristic, the presence of multiple EGF-like domains in TANGO 331 indicates that TANGO 331 is involved in binding to proteins extracellularly.

Post-translational hydroxylation of aspartic acid or asparagine to form erythro- β -hydroxyaspartic acid or erythro- β -hydroxyasparagine occurs in various proteins having one or more EGF-like domains (e.g., blood coagulation protein factors VII, IX, and X, blood coagulation proteins C, S, and Z, the LDL receptor, thrombomodulin, and the like). TANGO 331 has a signature sequence which is characteristic of hydroxylation of the asparagine residue at amino acid residue 310. The invention thus

includes TANGO 331 proteins having a hydroxylated asparagine residue at position 310 of SEQ ID NO: 326.

5 TNFR/NGFR (tumor necrosis factor receptor/nerve growth factor receptor) cysteine-rich region domains are about 30 to 40 amino acid residues in length, and generally exhibit a conserved pattern of six or more cysteine residues. These domains occur in several soluble and transmembrane proteins which are known to be receptors for growth factors or for cytokines. Examples of TNFR/NGFR cysteine-rich region domain-containing proteins are human tumor necrosis factor (TNF) cysteine-rich region domains type I and type II receptors, Shope fibroma virus soluble TNF receptor, 10 human lymphotoxin α/β , human low-affinity nerve growth factor receptor, human CD40L (cytokine) receptor CD40, human CD27L (cytokine) receptor CD27, human CD30L (cytokine) receptor CD30, human T-cell cytokine receptor 4-1BB, human apoptotic FASL protein receptor FAS, human T-cell OX40L (cytokine) receptor OX40, human apoptosis-related receptor Wsl-1, and Vaccinia protein A53. Presence 15 of a TNFR/NGFR cysteine-rich region domain in TANGO 331 is an indication that TANGO 331 is involved in one or more physiological processes involving extracellular binding with a cytokine or growth factor. Such processes include, for example, growth, homeostasis, regeneration, and proliferation of cells and tissues, immune (including autoimmune) responses, host defenses against infection, and the like.

20 Metallothioneins are cysteine-rich proteins which are capable of binding heavy metals such as calcium, zinc, copper, cadmium, cobalt, nickel, and the like. Proteins which have a domain which resembles a metal-binding domain of a metallothionein are also capable of binding such metals. TANGO 331 comprises a metallothionein-like domain, and is capable of binding one or more heavy metals. This is an indication that 25 TANGO 331 is involved in one or more physiological processes which involve metal binding. Such processes include, by way of example and not limitation, nutritional supply of metals to cells on a controlled basis, removal of toxic metal species from body tissues, storage of metals, and the like.

TANGO 331 comprises a leucine zipper region at about amino acid residue 94 to about amino acid residue 115 (i.e., 94 LeaqeehLeawwlqLkseydL 115; SEQ ID NO: 460). Leucine zipper regions are known to be involved in dimerization of proteins. Leucine zipper regions interact with one another, leading to formation of homo- or hetero-dimers between proteins, depending on their identity. The presence in TANGO 331 of a leucine zipper region is a further indication that this protein is involved in protein-protein interactions.

TANGO 331 shares amino acid and nucleic acid homology with a Chinese hamster protein designated HT, and thus is involved in corresponding physiological processes in humans. An alignment of the amino acid sequences of (human) TANGO 331 and Chinese hamster protein HT is shown in Figure 23E. In this alignment (made using the ALIGN software {Myers and Miller (1989) CABIOS, ver. 2.0}; pam120.mat scoring matrix; gap opening penalty = 12, gap extension penalty = 4), the proteins are 71.9% identical. An alignment of the nucleotide sequences of the ORFs encoding (human) TANGO 331 and Chinese hamster protein HT is shown in Figures 23F through 23J. The two ORFs are 74.5% identical, as assessed using the same software and parameters.

The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that human TANGO 331 protein includes an approximately 24 (i.e., 22, 23, 24, 25, or 26) amino acid residue signal peptide (amino acid residues 1 to 24 of SEQ ID NO: 326; SEQ ID NO: 327) preceding the mature TANGO 331 protein (i.e., approximately amino acid residues 25 to 353 of SEQ ID NO: 326; SEQ ID NO: 328). Mature human TANGO 331 is a secreted protein.

Figure 23D depicts a hydrophobicity plot of human TANGO 331 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to 24 of SEQ ID NO: 326 is the signal sequence of human TANGO 331 (SEQ ID NO: 327). As described elsewhere herein,

relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human TANGO 331 protein from about amino acid residue 140 to about amino acid residue 170 appears to be located at
5 or near the surface of the protein, while the region from about amino acid residue 115 to about amino acid residue 130 appears not to be located at or near the surface.

The predicted molecular weight of human TANGO 331 protein without modification and prior to cleavage of the signal sequence is about 38.2 kilodaltons. The predicted molecular weight of the mature human TANGO 331 protein without
10 modification and after cleavage of the signal sequence is about 35.6 kilodaltons.

Tissue distribution of TANGO 331 mRNA was determined by Northern blot hybridization. Northern blot hybridizations with the various RNA samples were performed using standard Northern blotting conditions and washing under stringent conditions (i.e., 0.2× SSC at 65°C). The DNA probe used in the Northern Blot
15 experiments was radioactively labeled with 32P-dCTP using the PRIME-IT™ kit (Stratagene, La Jolla, CA) according to the instructions of the supplier. Filters having human mRNA disposed thereon (MULTITISSUE™ Northern I and MULTITISSUE™ Northern II obtained from Clontech, Palo Alto, CA) were probed in EXPRESSHYB™ hybridization solution (Clontech) and washed at high stringency according to the
20 manufacturer's recommendations.

Two isoforms of human TANGO 331 were identified using this Northern blot analysis, indicating that TANGO 331 can have a splice variant. One isoform (corresponding to the larger message) can be a transmembrane protein (frizzled-like) and the other (i.e., smaller) isoform can be a secreted form. The two isoforms exhibit a
25 clear pattern of tissue specificity. On the multiple tissue blot from Clontech, the large transcript is found in almost all tissues, whereas the smaller message is expressed mainly in heart, skeletal muscle, placenta, and pancreas tissues.

TANGO 331 can be expressed as a recombinant glutathione-S-transferase (GST) fusion polypeptide in *E. coli* and the fusion polypeptide is isolated and characterized. Specifically, TANGO 331 can be fused with GST and this fusion polypeptide can be expressed in *E. coli*, e.g., in strain PEB199. Expression of the GST-TANGO 331 fusion protein in PEB199 is induced with IPTG. The recombinant fusion polypeptide can be purified from crude bacterial lysates of the induced PEB199 strain by affinity chromatography, e.g., using glutathione-substituted beads. Using polyacrylamide gel electrophoretic analysis of the polypeptide purified from the bacterial lysates, the molecular weight of the resultant fusion polypeptide can be determined.

To express the TANGO 331 gene in COS cells, the pcDNA/Amp vector by Invitrogen Corporation (San Diego, CA) can be used. This vector contains an SV40 origin of replication, an ampicillin resistance gene, an *E. coli* replication origin, a CMV promoter followed by a polylinker region, and an SV40 intron and polyadenylation site. A DNA fragment encoding the entire TANGO 331 protein and an HA tag (Wilson et al. (1984) Cell 37:767) or a FLAG tag fused in-frame to its 3' end of the fragment can be cloned into the polylinker region of the vector, thereby placing the expression of the recombinant protein under the control of the CMV promoter.

To construct the plasmid, the TANGO 331 DNA sequence is amplified by PCR using two primers. The 5' primer contains the restriction site of interest followed by approximately twenty nucleotides of the TANGO 331 coding sequence starting from the initiation codon; the 3' end sequence contains complementary sequences to the other restriction site of interest, a translation stop codon, the HA tag or FLAG tag and the last 20 nucleotides of the TANGO 331 coding sequence. The PCR amplified fragment and the pcDNA/Amp vector are digested with the appropriate restriction enzymes and the vector is dephosphorylated using the CIAP enzyme (New England Biolabs, Beverly, MA). Preferably the two restriction sites chosen are different so that the TANGO 331 gene is inserted in the correct orientation. The ligation mixture is

transformed into *E. coli* cells (e.g., one or more of strains HB101, DH5a, SURE, available from Stratagene Cloning Systems, La Jolla, CA), the transformed culture is plated on ampicillin media plates, and resistant colonies are selected. Plasmid DNA is isolated from transformants and examined by restriction analysis for the presence of the correct fragment.

COS cells are subsequently transfected using the TANGO 331-pcDNA/Amp plasmid DNA using the calcium phosphate or calcium chloride co-precipitation methods, DEAE-dextran-mediated transfection, lipofection, or electroporation. Other suitable methods of transfecting host cells can be found in Sambrook, J., Fritsh, E. F., and Maniatis, T. *Molecular Cloning: A Laboratory Manual*. 2nd, ed., Cold Spring Harbor Laboratory, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY, 1989. The expression of the TANGO 331 polypeptide can be detected by radiolabelling (^{35}S -methionine or ^{35}S -cysteine available from NEN, Boston, MA, can be used) and immunoprecipitation (Harlow, E. and Lane, D. *Antibodies: A Laboratory Manual*, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY, 1988) using an HA specific monoclonal antibody. Briefly, the cells are labeled for 8 hours with ^{35}S -methionine (or ^{35}S -cysteine). The culture media are then collected and the cells are lysed using detergents (RIPA buffer, 150 millimolar NaCl, 1% NP-40, 0.1% SDS, 0.5% DOC, 50 millimolar Tris, pH 7.5). Both the cell lysate and the culture media are precipitated with an HA specific monoclonal antibody. Precipitated polypeptides are then analyzed by SDS-PAGE.

Alternatively, DNA containing the TANGO 331 coding sequence can be cloned directly into the polylinker of the pCDNA/Amp vector using the appropriate restriction sites. The resulting plasmid is transfected into COS cells in the manner described above, and the expression of the TANGO 331 polypeptide can be detected by radiolabelling and immunoprecipitation using an TANGO 331 specific monoclonal antibody.

The human TANGO 331 gene was mapped using the Genebridge 4 Human Radiation hybrid mapping panel with ATTATTCAGAAGGATGTCCCGTGG (SEQ ID NO: 369) as the forward primer and CCTCCTGATTACCTACAATGGTC (SEQ ID NO: 370) as the reverse primer. The human TANGO 331 gene maps to human 22q11-q13. Flanking markers for this region are WI-4572 and WI-8917. The schizophrenia 4 (sczd4) locus also maps to this region of the human chromosome. Also mapping to this region of the human chromosome are the following genes: transcription factor 20 (tcf20), Benzodiazepine receptor, peripheral type (bzip), Arylsulfatase A (arsa), diaphorase (NADH); cytochrome b-5 reductase (dia1), and Solute carrier family 5 (sodium/glucose transporter), member 1 (slca1). This region is syntenic to mouse chromosome 15. The stargazer (stg), gray tremor (gt), brachyury modifier 2 (Brm2), bronchial hyperresponsiveness 2 (Bhr2), loss of righting induced by ethanol 5 (Lore5), fluctuating asymmetry QTL 8 (Faq8), jerky (Jrk), belted (bt), and koala (Koa) loci also map to this region of the mouse chromosome, several of which are neuromuscular related.

Uses of TANGO 331 Nucleic acids, Polypeptides, and Modulators Thereof

TANGO 331 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not expressed. Based on the observation that TANGO 331 is expressed in human mammary epithelial tissue and human heart tissue, TANGO 331 protein is involved in one or more biological processes which occur in mammary epithelial tissue, in other epithelial tissues, and in heart tissue. In particular, TANGO 331 is involved in modulating growth, proliferation, survival, differentiation, and activity of cells including, but not limited to, epithelial cells (e.g., mammary epithelial cells) of the animal in which it is normally expressed. Thus, TANGO 331 has a role in disorders which affect these cells and their growth, proliferation, survival, differentiation, and

activity. TANGO 331 is therefore involved in physiological processes such as maintenance of epithelia, carcinogenesis, modulation and storage of protein factors and metals, and lactation. Furthermore, because TANGO 331 is expressed in human mammary epithelial cells, it also has a role in nutrition of human infants (e.g.,
5 providing nutrients such as minerals to infants and providing protein factors not synthesized by infants) and in disorders which affect them. Thus, TANGO 331 is involved in a number of disorders such as breast cancer, insufficient lactation, infant nutritional and growth disorders, and the like. TANGO 331 polypeptides, nucleic acids, or modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or
10 alleviate one or more of these disorders.

Because TANGO 331 exhibits expression in the heart, TANGO 331 nucleic acids, proteins, and modulators thereof can be used to treat cardiovascular disorders. Examples of cardiovascular disorders with which TANGO 331 can be involved include those described elsewhere in this disclosure. TANGO 331 polypeptides, nucleic acids,
15 or modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

In another example, TANGO 331 polypeptides, nucleic acids, and modulators thereof, can be involved in normal and aberrant functioning of skeletal muscle tissue, and can thus be involved in disorders of such tissue. Examples of skeletal muscle
20 disorders are described elsewhere in this disclosure. TANGO 331 polypeptides, nucleic acids, or modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

In another example, TANGO 331 polypeptides, nucleic acids, and modulators thereof can be used to treat placental disorders, such as those described elsewhere in this disclosure. TANGO 331 polypeptides, nucleic acids, or modulators thereof can be
25 used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

Presence in TANGO 331 of numerous EGF-like domains, including the laminin-like EGF-like domain indicates that TANGO 331 is involved in extracellular binding of proteins, including both other secreted proteins (e.g., growth factors and cytokines) and cell-surface proteins. Binding of TANGO 331 to other secreted proteins modulates their activity, their rate of uptake by cells, and their rate of degradation. Binding of TANGO 331 to cell surface proteins modulates their activity, including, for example, their ability to bind with other secreted proteins, and transmits a signal to the cell expressing the cell-surface protein. Presence in TANGO 331 of a TNFR/NGFR cysteine-rich region domain is further indicative of the ability of TANGO 331 to bind with growth factors and cytokines. Thus, TANGO 331 is involved in a number of proliferative and immune disorders including, but not limited to, cancers (e.g., breast cancer), autoimmune disorders, insufficient or inappropriate host responses to infection, acquired immune deficiency syndrome, and the like. TANGO 331 polypeptides, nucleic acids, or modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

The fact that TANGO 331 has a metallothionein-like region is indicative of the ability of TANGO 331 to bind with metal ions, including nutritionally required metal ions (e.g., calcium, magnesium, zinc, manganese, cobalt, iron, and the like). Thus, TANGO 331 is involved in binding with essential minerals and in delivering them to their proper body locations. TANGO 331 is also involved in binding excess or toxic metal ions so that they can be excreted. TANGO 331 is thus involved in disorders involving insufficient or inappropriate localization of metal ions. Such disorders include, but are not limited to, malnutrition and mineral deficiency disorders, hemochromatosis, inappropriate calcification of body tissues, bone disorders such as osteoporosis, and the like. TANGO 331 polypeptides, nucleic acids, or modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

Mapping of the human TANGO 331 gene to chromosomal region 22q11-q13 is an indication of disorders with which its expression (or non- or aberrant-expression) can be associated. For example, arylsulfatase A is associated with Metachromatic leukodystrophy. Diaphorase (NADH:cytochrome b-5 reductase) is associated with methemoglobinemia, types I and II. Solute carrier family 5 (sodium/glucose transporter), member 1 is associated with glucose/galactose malabsorption. The gene designated schizophrenia 4 is associated with schizophrenia and velocardiofacial syndrome, as described in Online Mendelian Inheritance in Man, Johns Hopkins University, Baltimore, MD. MIM Number: 600850:12/7/98. (World Wide Web URL: <http://www.ncbi.nlm.nih.gov/omim/>). These mapping data indicate that TANGO 331 polypeptides, nucleic acids, and modulators thereof can be used to prognosticate, diagnose, inhibit, prevent, or alleviate one or more of these disorders.

TANGO 332

A cDNA clone (designated jlhbab463g12) encoding at least a portion of human TANGO 332 protein was isolated from a human adult brain cDNA library. The human TANGO 332 protein is predicted by structural analysis to be a secreted protein.

The full length of the cDNA encoding human TANGO 332 protein (Figure 24; SEQ ID NO: 329) is 2730 nucleotide residues. The ORF of this cDNA, nucleotide residues 173 to 2185 of SEQ ID NO: 329 (i.e., SEQ ID NO: 330), encodes a 671-amino acid transmembrane protein (Figure 24; SEQ ID NO: 331).

The invention thus includes purified human TANGO 332 protein, both in the form of the immature 671 amino acid residue protein (SEQ ID NO: 331) and in the form of the mature, approximately 649 amino acid residue protein (SEQ ID NO: 333). Mature human TANGO 332 protein can be synthesized without the signal sequence polypeptide at the amino terminus thereof, or it can be synthesized by generating immature TANGO 332 protein and cleaving the signal sequence therefrom.

The invention includes nucleic acid molecules which encode a TANGO 332 polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the nucleotide sequence listed in SEQ ID NO: 329 or some portion thereof, such as the portion which encodes mature TANGO 332 protein, immature
5 TANGO 332 protein, or a domain of TANGO 332 protein. These nucleic acids are collectively referred to as TANGO 332 nucleic acids of the invention.

TANGO 332 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional features, as indicated by the conservation of amino acid sequence between human TANGO 332
10 protein, human brain-enriched hyaluronan-binding factor (BEF), as shown in Figures 24G and 24H, and murine brevican protein, as shown in Figures 24I to 24K. This conservation is further indicated by conservation of nucleotide sequence between the ORFs encoding human TANGO 332 protein and murine brevican protein, as shown in Figures 24L through 24U.

15 A common domain present in TANGO 332 proteins is a signal sequence. In one embodiment, a TANGO 332 protein contains a signal sequence corresponding to about amino acid residues 1 to 22 of SEQ ID NO: 331 (SEQ ID NO: 332). The signal sequence is cleaved during processing of the mature protein.

TANGO 332 proteins are secreted proteins. The mature form of human
20 TANGO 332 protein has the amino acid sequence of approximately amino acid residues 23 to 671 of SEQ ID NO: 331.

TANGO 332 proteins typically comprise a variety of potential post-translational modification sites (often within an extracellular domain), such as those described herein in Table XXIII, as predicted by computerized sequence analysis of
25 TANGO 332 proteins using amino acid sequence comparison software (comparing the amino acid sequence of TANGO 332 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}). In

certain embodiments, a protein of the invention has at least 1, 2, 4, 6, 10, 15, or 20 or more of the post-translational modification sites listed in Table XXIII.

Table XXIII

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 331	Amino Acid Sequence
N-glycosylation site	130 to 133	NDSG
	337 to 340	NQTG
Protein kinase C phosphorylation site	67 to 69	SRR
	74 to 76	SPR
	165 to 167	SAR
	212 to 214	TVR
	219 to 221	TPR
	310 to 312	SVR
	319 to 321	SQR
	545 to 547	TPR
Casein kinase II phosphorylation site	615 to 617	SGR
	29 to 32	SSSD
	116 to 119	SLTD
	219 to 222	TPRE
	269 to 272	TLEE
	382 to 385	TVTE
	386 to 389	TLEE
	397 to 400	TESE
	419 to 422	STPE
	430 to 433	TLLE
	446 to 449	SEEE
	545 to 548	TPRE
	558 to 561	TLVE

Table XXIII (Continued)

Tyrosine kinase phosphorylation site	128 to 135	RPNDSGIY
	451 to 459	KALEEEEEKY
N-myristoylation site	47 to 52	GVLGGA
	133 to 138	GIYRCE
	142 to 147	GIDDSS
	174 to 179	GAQEAC
	183 to 188	GAHIAT
	281 to 286	GAEIAT
	288 to 293	GQLYAA
	297 to 302	GLDHCS
	324 to 329	GGLPGV
	403 to 408	GAIYSI
	414 to 419	GGGGSS
	576 to 581	GVPRGE
Immunoglobulin-/major histocompatibility protein-like (Ig-/MHC-like) domain	586 to 591	GSSEGA
	50 to 141	See Fig. 24
Extracellular link domain	156 to 251	See Fig. 24
	257 to 353	See Fig. 24

Among the domains that occur in TANGO 332 protein are an Ig-/MHC-like domain and a pair of extracellular link domains. In one embodiment, the protein of the invention has at least one domain that is at least 55%, preferably at least about 65%, more preferably at least about 75%, yet more preferably at least about 85%, and most preferably at least about 95% identical to one of these domains. In other embodiments,

the protein has at least one Ig-/MHC-like domain and one extracellular link domain described herein in Table XXIII. In other embodiments, the protein has at least one Ig-/MHC-like domain and at least two extracellular link domains.

5 Ig-/MHC-like domains are conserved among immunoglobulin (Ig) constant (CL) regions and one of the three extracellular domains of major histocompatibility proteins (MHC). The presence in TANGO 332 of an Ig-/MHC-like domain indicates that the corresponding region of TANGO 332 is structurally similar to this conserved extracellular region.

Extracellular link domains occur in hyaluronan- (HA-)binding proteins.

10 Proteins having this domain include cartilage link protein, proteoglycans such as aggrecan, brevican, neurocan, and versican, CD44 antigen (the primary cell surface receptor for HA), and tumor necrosis factor-inducible protein TSG-6. Presence of a pair of extracellular link domains in TANGO 332 indicates that this protein is also involved in HA-binding, and therefore is involved in physiological processes such as

15 cartilage (and other tissue) organization, extracellular matrix organization, neural growth and branching, and cell-to-cell and cell-to-matrix interactions. Involvement of TANGO 332 in these processes implicates this protein in disorders such as tumor growth and metastasis, movement of cells (e.g., leukocytes) through extracellular matrix, inappropriate inflammation, and the like.

20 Brevican is a murine nervous system-specific chondroitin sulfate proteoglycan which binds in a calcium-dependent manner with two classes of sulfated glycolipids, namely sulfatides and HNK-1-reactive sulfoglucuronylglycolipids (Miura et al. (1999) J. Biol. Chem. 274:11431-11438). A human orthologue, designated BEF ('Brain-Enriched hyaluronan-binding Factor'), of murine brevican is expressed by human

25 glioma cells, but not by brain tumors of non-glial origin (P.C.T. application publication number WO98/31800; Zhang et al. (1998) J. Neurosci. 18:2370-2376). Those authors suggested that cleavage of that human orthologue mediates glioma cell invasion in vivo.

An alignment of the amino acid sequences of TANGO 332 and BEF protein is shown in Figures 24G and 24H. In this alignment (made using the ALIGN software {Myers and Miller (1989) CABIOS, ver. 2.0}; pam120.mat scoring matrix; gap opening penalty = 12, gap extension penalty = 4), the proteins are 75.7% identical, although it is seen that TANGO 332 includes two domains (one from about amino acid residue 152 to about residue 208, and the other near the carboxyl terminus of TANGO 332) which do not occur in BEF protein. It is likely that these two regions account for the differences between the physiological roles of TANGO 332 and BEF.

An alignment of the amino acid sequences of (human) TANGO 332 and murine brevicin protein is shown in Figures 24I through 24K. In this alignment (made using the ALIGN software {Myers and Miller (1989) CABIOS, ver. 2.0}; pam120.mat scoring matrix; gap opening penalty = 12, gap extension penalty = 4), the proteins are 75.5% identical, although it is seen that murine brevicin protein includes a domain which does not occur in TANGO 332 protein, this domain is present from about amino acid residue 626 to the carboxyl terminus of murine brevicin protein. An alignment of the nucleotide sequences of the ORFs encoding (human) TANGO 332 and murine brevicin protein is shown in Figures 24L through 24U. The two ORFs are 62.6% identical, as assessed using the same software and parameters.

TANGO 332 exhibits many of the same properties as BEF. TANGO 332 is also related to murine brevicin protein, and thus is involved with corresponding physiological processes (i.e., such as those described above) in humans. For example, TANGO 332 modulates intracellular binding and migration of cells in a tissue or extracellular matrix. However, the absence from BEF of one of the two extracellular link domains present in TANGO 332 indicates that one or more of the subunit structure, the tissue specificity, and the binding specificity of TANGO 332 and BEF proteins differ. Thus, TANGO 332 is involved in many of the physiological processes and disorders in which BEF protein is involved. Like murine brevicin and other proteoglycans, TANGO 332 acts in vivo as a tissue organizing protein, influences

growth and maturation of tissues in which it is expressed, modulates growth factor-mediated activities, modulates structural features of tissues (e.g., collagen fibrillogenesis), modulates tumor cell growth and invasivity, and influences neurite growth and branching.

5 The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that human TANGO 332 protein includes an approximately 22 (i.e., 20, 21, 22, 23, or 24) amino acid residue signal peptide (amino acid residues 1 to 22 of SEQ ID NO: 331; SEQ ID NO: 332) preceding the mature TANGO 332 protein (i.e., approximately amino acid residues 23 to 671 of SEQ ID
10 NO: 331; SEQ ID NO: 333). Human TANGO 332 protein is a secreted protein, as assessed using the secretion assay described herein. Secreted TANGO 332 proteins having approximate sizes of 148 kilodaltons and 100 kilodaltons could be detected using this assay.

 Figure 24F depicts a hydrophobicity plot of human TANGO 332 protein.
15 Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to 22 of SEQ ID NO: 331 is the signal sequence of human TANGO 332 (SEQ ID NO: 332). As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein,
20 and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human TANGO 332 protein from about amino acid residue 445 to about amino acid residue 475 appears to be located at or near the surface of the protein, while the region from about amino acid residue 45 to about amino acid residue 62 appears not to be located at or near the surface.

25 The predicted molecular weight of human TANGO 332 protein without modification and prior to cleavage of the signal sequence is about 71.7 kilodaltons. The predicted molecular weight of the mature human TANGO 332 protein without modification and after cleavage of the signal sequence is about 69.5 kilodaltons.

Uses of TANGO 332 Nucleic acids,
Polypeptides, and Modulators Thereof

TANGO 332 proteins are involved in disorders which affect both tissues in
5 which they are normally expressed and tissues in which they are normally not
expressed. Based on the observation that TANGO 332 is expressed in human adult
brain tissue, TANGO 332 protein is involved in one or more biological processes
which occur in these tissues. In particular, TANGO 332 is involved in modulating
growth, proliferation, survival, differentiation, and activity of cells including, but not
10 limited to, adult brain cells of the animal in which it is normally expressed. Thus,
TANGO 332 has a role in disorders which affect these cells and their growth,
proliferation, survival, differentiation, interaction, and activity. Examples of such
disorders include, by way of example and not limitation, disorders of neural connection
establishment or maintenance, impaired cognitive function, dementia, senility,
15 Alzheimer's disease, mental retardation, brain tumors (e.g., gliomas such as
astrocytomas, endophytic and exophytic retinoblastomas, ependymomas,
gangliogliomas, mixed gliomas, nasal gliomas, optic gliomas, and Schwannomas, and
other brain cell tumors such as medulloblastomas, pituitary adenomas, teratomas, etc.),
and the like. TANGO 332 can also be involved in the other brain disorders described
20 elsewhere in this disclosure.

Homology of human TANGO 332 with murine brevican protein and with
human brevican homolog BEF indicates that TANGO 332 has physiological functions
in humans analogous to the functions of these proteins. Brevican is a member of the
aggrecan/versican family of proteoglycans, and has a hyaluronic acid-binding domain
25 in its amino terminal region and a lectin-like domain in its carboxyl terminal region.
Expression of brevican is highly specific to brain tissue, and increases as the
mammalian brain develops. Thus, brevican is involved in maintaining the extracellular
environment of mature brain tissue and is a constituent of adult brain extracellular

matrix. TANGO 332 is involved in modulating cell-to-cell adhesion, tissue and extracellular matrix invasivity of cells, and the like. Thus, TANGO 332 is involved in disorders in which these physiological processes are relevant. Such disorders include, for example, loss of control of cell growth, tumor metastasis, malformation of neurological connections, inflammation, immune and autoimmune responses, and the like.

In addition, presence in TANGO 332 of extracellular link domains indicates that this protein is involved in physiological processes involving structure and function of extracellular matrices and interaction of cells with such matrices and with each other. This is further evidence that TANGO 332 is involved in disorders such as inappropriate inflammation, tumor metastasis, inappropriate leukocyte extravasation, localization, and reactivity, and the like.

TANGO 332-related molecules can be used to modulate one or more of the activities in which TANGO 332 is involved and can also be used to prevent, diagnose, or treat one or more of the disorders in which TANGO 332 is involved.

TANGO 202

A cDNA clone (designated jthke096b05) encoding at least a portion of human TANGO 202 protein was isolated from a human fetal skin cDNA library. The corresponding murine cDNA was isolated as a clone (designated jtmMa044f07) from a bone marrow stromal cell cDNA library. The human TANGO 202 protein is predicted by structural analysis to be a type I membrane protein, although it can exist in a secreted form as well. The murine TANGO 202 protein is predicted by structural analysis to be a secreted protein.

The full length of the cDNA encoding human TANGO 202 protein (Figure 25; SEQ ID NO: 371) is 1656 nucleotide residues. The open reading frame (ORF) of this cDNA, nucleotide residues 34 to 1458 of SEQ ID NO: 371 (i.e., SEQ ID NO: 372), encodes a 475-amino acid transmembrane protein (Figure 25; SEQ ID NO: 373).

The invention thus includes purified human TANGO 202 protein, both in the form of the immature 475 amino acid residue protein (SEQ ID NO: 373) and in the form of the mature 456 amino acid residue protein (SEQ ID NO: 375). The invention also includes purified murine TANGO 202 protein, both in the form of the immature
5 470 amino acid residue protein (SEQ ID NO: 439) and in the form of the mature 451 amino acid residue protein (SEQ ID NO: 413). Mature human or murine TANGO 202 proteins can be synthesized without the signal sequence polypeptide at the amino terminus thereof, or they can be synthesized by generating immature TANGO 202 protein and cleaving the signal sequence therefrom.

10 The invention includes nucleic acid molecules which encode a polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the nucleotide sequence listed in SEQ ID NO: 371 or some portion thereof or SEQ ID NO: 439 or some portion thereof, such as the portion which encodes mature human or murine TANGO 202 protein, immature human or murine TANGO 202 protein, or a
15 domain of human or murine TANGO 202 protein. These nucleic acids are collectively referred to as nucleic acids of the invention.

TANGO 202 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional features.

A common domain present in TANGO 202 proteins is a signal sequence. In
20 one embodiment, a TANGO 202 protein contains a signal sequence corresponding to amino acid residues 1 to 19 of SEQ ID NO: 373 (SEQ ID NO: 374) or to amino acid residues 1 to 19 of SEQ ID NO: 439 (SEQ ID NO: 412). The signal sequence is cleaved during processing of the mature protein.

TANGO 202 proteins can also include an extracellular domain. The human
25 TANGO 202 protein extracellular domain is located from about amino acid residue 20 to about amino acid residue 392 of SEQ ID NO: 373 in the non-secreted form, and from about amino acid residue 20 to amino acid residue 475 of SEQ ID NO: 373 (i.e., the entire mature human protein). The murine TANGO 202 protein extracellular

domain is located from about amino acid residue 20 to amino acid residue 470 of SEQ ID NO: 439 (i.e., the entire mature murine protein).

TANGO 202 proteins of the invention can also include a transmembrane domain. As used herein, a "transmembrane domain" refers to an amino acid sequence
5 having at least about 20 to 25 amino acid residues in length and which contains at least about 65-70% hydrophobic amino acid residues such as alanine, leucine, phenylalanine, protein, tyrosine, tryptophan, or valine. In a preferred embodiment, a transmembrane domain contains at least about 15 to 30 amino acid residues, preferably about 20-25 amino acid residues, and has at least about 60-80%, more preferably 65-
10 75%, and more preferably at least about 70% hydrophobic residues. Thus, in one embodiment, a TANGO 202 protein of the invention contains a transmembrane domain corresponding to about amino acid residues 393 to 415 of SEQ ID NO: 373 (SEQ ID NO: 377).

In addition, TANGO 202 proteins of the invention can include a cytoplasmic
15 domain, particularly including a carboxyl-terminal cytoplasmic domain. The cytoplasmic domain is located from about amino acid residue 416 to amino acid residue 475 of SEQ ID NO: 373 (SEQ ID NO: 378) in the non-secreted form of human TANGO 202 protein.

TANGO 202 proteins typically comprise a variety of potential post-
20 translational modification sites (often within an extracellular domain), such as those described herein in Tables XXIV (for human TANGO 202) and XXV (for murine TANGO 202), as predicted by computerized sequence analysis of TANGO 202 proteins using amino acid sequence comparison software (comparing the amino acid sequence of TANGO 202 with the information in the PROSITE database {rel. 12.2;
25 Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}).

CUB domain	214 to 318	See Fig. 25

In various embodiments, the protein of the invention has at least 1, 2, 4, 6, 10,
5 15, or 20 or more of the post-translational modification sites described herein in Tables XXIV and XXV.

Examples of additional domains present in human and murine TANGO 202 protein include Kringle domains and CUB domains. In one embodiment, the protein of the invention has at least one domain that is at least 55%, preferably at least about
10 65%, more preferably at least about 75%, yet more preferably at least about 85%, and most preferably at least about 95% identical to one of the domains described herein in Tables XXIV and XXV. Preferably, the protein of the invention has at least one Kringle domain and one CUB domain.

A Kringle domain has a characteristic profile that has been described in the art
15 (Castellino and Beals (1987) J. Mol. Evol. 26:358-369; Patthy (1985) Cell 41:657-663; Ikeo et al. (1991) FEBS Lett. 287:146-148). Many, but not all, Kringle domains comprise a conserved hexapeptide signature sequence, namely

(F or Y) - C - R - N - P - (D or N or R) (SEQ ID NO: 455).

The cysteine residue is involved in a disulfide bond.

20 Kringle domains are triple-looped, disulfide cross-linked domains found in a varying number of copies in, for example, some serine proteases and plasma proteins. Kringle domains have a role in binding mediators (e.g., membranes, other proteins, or phospholipids) and in regulation of proteolytic activity. Kringle domains have been identified in the following proteins, for example: apolipoprotein A, blood coagulation
25 factor XII (Hageman factor), hepatocyte growth factor (HGF), HGF-like protein (Friezner Degen et al., (1991) Biochemistry 30:9781-9791), HGF activator (Miyazawa

et al., (1993) J. Biol. Chem. 268:10024-10028), plasminogen, thrombin, tissue plasminogen activator, urokinase-type plasminogen activator, and four influenza neuraminidases. The presence of a Kringle domain in each of human and murine TANGO 202 protein indicates that TANGO 202 is involved in one or more

5 physiological processes in which these other Kringle domain-containing proteins are involved, has biological activity in common with one or more of these other Kringle domain-containing proteins, or both.

CUB domains are extracellular domains of about 110 amino acid residues which occur in functionally diverse, mostly developmentally regulated proteins (Bork and Beckmann (1993) J. Mol. Biol. 231:539-545; Bork (1991) FEBS Lett. 282:9-12). Many CUB domains contain four conserved cysteine residues, although some, like that of TANGO 202, contain only two of the conserved cysteine residues. The structure of the CUB domain has been predicted to assume a beta-barrel configuration, similar to that of immunoglobulins. Other proteins which have been found to comprise one or more CUB domains include, for example, mammalian complement sub-components C1s and C1r, hamster serine protease Casp, mammalian complement activating component of Ra-reactive factor, vertebrate enteropeptidase, vertebrate bone morphogenic protein 1, sea urchin blastula proteins BP10 and SpAN, *Caenorhabditis elegans* hypothetical proteins F42A10.8 and R151.5, neuropilin (A5 antigen), sea urchin fibropellins I and III, mammalian hyaluronate-binding protein TSG-6 (PS4), mammalian spermadhesins, and *Xenopus* embryonic protein UVS.2. The presence of a CUB domain in each of human and murine TANGO 202 protein indicates that TANGO 202 is involved in one or more physiological processes in which these other CUB domain-containing proteins are involved, has biological activity in common with one or more of these other CUB domain-containing proteins, or both.

The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that human TANGO 202 protein includes a 19 amino acid signal peptide (amino acid residues 1 to 19 of SEQ ID NO: 373; SEQ ID NO: 374)

preceding the mature TANGO 202 protein (amino acid residues 20 to 475 of SEQ ID NO: 373; SEQ ID NO: 375). Human TANGO 202 protein includes an extracellular domain (amino acid residues 20 to 392 of SEQ ID NO: 373; SEQ ID NO: 376); a transmembrane domain (amino acid residues 393 to 415 of SEQ ID NO: 373; SEQ ID NO: 377); and a cytoplasmic domain (amino acid residues 416 to 475 of SEQ ID NO: 373; SEQ ID NO: 378). The murine homolog of TANGO 202 protein is predicted to be a secreted protein. Thus, it is recognized that human TANGO 202 can also exist in the form of a secreted protein, likely being translated from an alternatively spliced TANGO 202 mRNA. In a variant form of the protein, an extracellular portion of TANGO 202 protein (e.g., amino acid residues 20 to 392 of SEQ ID NO: 373) can be cleaved from the mature protein to generate a soluble fragment of TANGO 202.

Figure 25L depicts a hydrophobicity plot of human TANGO 202 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to 19 of SEQ ID NO: 373 is the signal sequence of human TANGO 202 (SEQ ID NO: 374). The hydrophobic region which corresponds to amino acid residues 393 to 415 of SEQ ID NO: 373 is the transmembrane domain of human TANGO 202 (SEQ ID NO: 377). As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human TANGO 202 protein from about amino acid residue 61 to about amino acid residue 95 appears to be located at or near the surface of the protein, while the region from about amino acid residue 395 to about amino acid residue 420 appears not to be located at or near the surface.

The predicted molecular weight of human TANGO 202 protein without modification and prior to cleavage of the signal sequence is about 51.9 kilodaltons.

The predicted molecular weight of the mature human TANGO 202 protein without modification and after cleavage of the signal sequence is about 50.1 kilodaltons.

The full length of the cDNA encoding murine TANGO 202 protein (Figure 25; SEQ ID NO: 437) is 4928 nucleotide residues. The ORF of this cDNA, nucleotide
5 residues 81 to 1490 of SEQ ID NO: 437 (i.e., SEQ ID NO: 438), encodes a 470-amino acid secreted protein (Figure 25; SEQ ID NO: 439).

The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that murine TANGO 202 protein includes a 19 amino acid signal peptide (amino acid residues 1 to 19 of SEQ ID NO: 439; SEQ ID NO: 412)
10 preceding the mature TANGO 202 protein (amino acid residues 20 to 470 of SEQ ID NO: 439; SEQ ID NO: 413). Murine TANGO 202 protein is a secreted protein.

Figure 25M depicts a hydrophobicity plot of murine TANGO 202 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region
15 which corresponds to amino acid residues 1 to 19 of SEQ ID NO: 439 is the signal sequence of murine TANGO 202 (SEQ ID NO: 412). As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of murine TANGO 202 protein from
20 about amino acid residue 61 to about amino acid residue 95 appears to be located at or near the surface of the protein, while the region from about amino acid residue 295 to about amino acid residue 305 appears not to be located at or near the surface

The predicted molecular weight of murine TANGO 202 protein without modification and prior to cleavage of the signal sequence is about 51.5 kilodaltons.
25 The predicted molecular weight of the mature murine TANGO 202 protein without modification and after cleavage of the signal sequence is about 49.7 kilodaltons.

Human and murine TANGO 202 proteins exhibit considerable sequence similarity, as indicated herein in Figures 25J and 25K. Figures 25J and 25K depict an

alignment of human and murine TANGO 202 amino acid sequences (SEQ ID NOs: 373 and 439, respectively). In this alignment (made using the ALIGN software {Myers and Miller (1989) CABIOS, ver. 2.0}; pam120.mat scoring matrix; gap penalties -12/-4), the proteins are 76.5% identical. The human and murine ORFs
5 encoding TANGO 202 are 87.4% identical, as assessed using the same software and parameters.

In situ hybridization experiments in mouse tissues indicated that mRNA corresponding to the cDNA encoding TANGO 202 is expressed in the tissues listed in Table XXVI, wherein "+" indicates detectable expression and "++" indicates a greater
10 level of expression than "+".

Table XXVI

Animal	Tissue	Relative Level of Expression
Mouse (Adult)	bladder, especially in transitional epithelium	++
	renal glomeruli	+
	brain	+
	heart	+
	liver	+
	spleen	+
	placenta	+
Mouse (Embryo)	ubiquitous	+

Uses of TANGO 202 Nucleic acids,
Polypeptides, and Modulators Thereof

TANGO 202 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not expressed. Based on the observation that TANGO 202 is expressed in human fetal skin, ubiquitously in fetal mouse tissues, in adult murine bone marrow stromal cells, and in cells of adult murine bladder, renal glomeruli, brain, heart, liver, spleen and placenta, TANGO 202 protein is involved in one or more biological processes which occur in these tissues. In particular, TANGO 202 is involved in modulating growth, proliferation, survival, differentiation, and activity of cells of these tissues including, but not limited to, hematopoietic and fetal cells. Thus, TANGO 202 has a role in disorders which affect these cells and their growth, proliferation, survival, differentiation, and activity. Ubiquitous expression of TANGO 202 in fetal murine tissues, contrasted with limited expression in adult murine tissues further indicates that TANGO 202 is involved in disorders in which it is inappropriately expressed (e.g., disorders in which TANGO 202 is expressed in adult murine tissues other than bone marrow stromal cells and disorders in which TANGO 202 is not expressed in one or more developing fetal tissues).

The presence of a Kringle domain in both the murine and human TANGO 202 proteins indicates that this protein is involved in modulating cellular binding to one or more mediators (e.g., proteins, phospholipids, intracellular organelles, or other cells), in modulating proteolytic activity, or both. The presence of a Kringle domain in other proteins (e.g., growth factors) indicates activities that these proteins share with TANGO 202 protein (e.g., modulating cell dissociation and migration into and through extracellular matrices). The presence of Kringle domains in numerous plasma proteins, particularly coupled with the observation that TANGO 202 is expressed in adult murine bone marrow stromal cells, indicates a role for TANGO 202 protein in modulating binding of blood or hematopoietic cells (or both) to one or more mediators.

Thus, TANGO 202 is involved in disorders relating to aberrant cellular protease activity, inappropriate interaction or non-interaction of cells with mediators, and in blood and hematopoietic cell-related disorders. Such disorders include, by way of example and not limitation, immune disorders, infectious diseases, auto-immune disorders, vascular and cardiovascular disorders, disorders related to mal-expression of growth factors, cancers, hematological disorders, and the like.

The cDNA encoding TANGO 202 exhibits significant nucleotide sequence similarity with a polynucleotide encoding a kringle-domain-containing protein (designated HTHBZ47) described in the European Patent Application No. EP 0 911 399 A2 (published April 28, 1999). Thus, the TANGO 202 protein can exhibit one or more of the activities exhibited by HTHBZ47, and can be used to prevent, inhibit, diagnose, and treat one or more disorders for which HTHBZ47 is useful. These disorders include cancer, inflammation, autoimmune disorders, allergic disorders, asthma, rheumatoid arthritis, inflammation of central nervous system tissues, cerebellar degeneration, Alzheimer's disease, Parkinson's disease, multiple sclerosis, amyotrophic lateral sclerosis, head injury damage and other neurological abnormalities, septic shock, sepsis, stroke, osteoporosis, osteoarthritis, ischemic reperfusion injury, cardiovascular disease, kidney disease, liver disease, ischemic injury, myocardial infarction, hypotension, hypertension, AIDS, myelodysplastic syndromes and other hematologic abnormalities, aplastic anemia, male pattern baldness, and bacterial, fungal, protozoan, and viral infections.

The presence of a CUB domain in both the murine and human TANGO 202 proteins indicates that this protein is involved in biological processes common to other CUB domain-containing proteins, such as developmental processes and binding to mediators. Therefore, TANGO 202 protein has a role in disorders which involve inappropriate developmental processes (e.g., abnormally high proliferation or undifferentiation of a differentiated tissue or abnormally low differentiation or proliferation of a non-developed or non-differentiated tissue) and modulation of cell

growth, proliferation, survival, differentiation, and activity. Such disorders include, by way of example and not limitation, various cancers and birth and developmental defects.

Thus, proteins and nucleic acids of the invention which are identical to, similar
5 to, or derived from human and murine TANGO 202 proteins and nucleic acids encoding them are useful for preventing, diagnosing, and treating, among others, vascular and cardiovascular disorders, hematological disorders, disorders related to mal-expression of growth factors, and cancer. Other uses for these proteins and nucleic acids of the invention relate to modulating cell growth (e.g., angiogenesis),
10 proliferation (e.g., cancers), survival (e.g., apoptosis), differentiation (e.g., hematopoiesis), and activity (e.g., ligand-binding capacity). TANGO 202 proteins and nucleic acids encoding them are also useful for modulating cell dissociation and modulating migration of cells in extracellular matrices.

15 TANGO 234

A cDNA clone (designated jthsa104d11) encoding at least a portion of human TANGO 234 protein was isolated from a human fetal spleen cDNA library. The human TANGO 234 protein is predicted by structural analysis to be a transmembrane protein, although it can exist in a secreted form as well.

20 The full length of the cDNA encoding human TANGO 234 protein (Figure 26; SEQ ID NO: 379) is 4628 nucleotide residues. The ORF of this cDNA, nucleotide residues 28 to 4386 of SEQ ID NO: 379 (i.e., SEQ ID NO: 380), encodes a 1453-amino acid transmembrane protein (Figure 26; SEQ ID NO: 381).

The invention thus includes purified human TANGO 234 protein, both in the
25 form of the immature 1453 amino acid residue protein (SEQ ID NO: 381) and in the form of the mature 1413 amino acid residue protein (SEQ ID NO: 383). Mature human TANGO 234 protein can be synthesized without the signal sequence

polypeptide at the amino terminus thereof, or it can be synthesized by generating immature TANGO 234 protein and cleaving the signal sequence therefrom.

The invention includes nucleic acid molecules which encode a polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the
5 nucleotide sequence listed in SEQ ID NO: 379 or some portion thereof, such as the portion which encodes mature TANGO 234 protein, immature TANGO 234 protein, or a domain of TANGO 234 protein. These nucleic acids are collectively referred to as nucleic acids of the invention.

TANGO 234 proteins and nucleic acid molecules encoding them comprise a
10 family of molecules having certain conserved structural and functional features, as indicated by the conservation of amino acid sequence between human TANGO 234 protein and bovine WC1 protein, as shown in Figures 26K through 26P, and the conservation of nucleotide sequence between the ORFs encoding human TANGO 234 protein and bovine WC1 protein, as shown in Figures 26Q-1 through 26Q-19.

15 A common domain present in TANGO 234 proteins is a signal sequence. In one embodiment, a TANGO 234 protein contains a signal sequence corresponding to amino acid residues 1 to 40 of SEQ ID NO: 381 (SEQ ID NO: 382). The signal sequence is cleaved during processing of the mature protein.

TANGO 234 proteins can include an extracellular domain. The human
20 TANGO 234 protein extracellular domain is located from about amino acid residue 41 to about amino acid residue 1359 of SEQ ID NO: 381. TANGO 234 can alternately exist in a secreted form, such as a mature protein having the amino acid sequence of amino acid residues 41 to 1453 or residues 41 to about 1359 of SEQ ID NO: 381.

In addition, TANGO 234 include a transmembrane domain. In one
25 embodiment, a TANGO 234 protein of the invention contains a transmembrane domain corresponding to about amino acid residues 1360 to 1383 of SEQ ID NO: 381 (SEQ ID NO: 385).

The present invention includes TANGO 234 proteins having a cytoplasmic domain, particularly including proteins having a carboxyl-terminal cytoplasmic domain. The human TANGO 234 cytoplasmic domain is located from about amino acid residue 1384 to amino acid residue 1453 of SEQ ID NO: 381 (SEQ ID NO: 386).

- 5 TANGO 234 proteins typically comprise a variety of potential post-translational modification sites (often within an extracellular domain), such as those described herein in Table XXVII, as predicted by computerized sequence analysis of TANGO 234 proteins using amino acid sequence comparison software (comparing the amino acid sequence of TANGO 234 with the information in the PROSITE database
- 10 {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}). In certain embodiments, a protein of the invention has at least 1, 2, 4, 6, 10, 15, or 20 or more of the post-translational modification sites listed in Table XXVII.

Among the domains that occur in TANGO 234 protein are SRR domains and
5 SRCR domains. In one embodiment, the protein of the invention has at least one
domain that is at least 55%, preferably at least about 65%, more preferably at least
about 75%, yet more preferably at least about 85%, and most preferably at least about
95% identical to one of these domains. In other embodiments, the protein has at least
two of the SRR and SRCR domains described herein in Table XXVII. In other
10 embodiments, the protein has at least one SRR domain and at least one SRCR domain.

The SRR domain is named after a receptor domain identified in a sea urchin egg protein designated speract. The consensus sequence of this domain (using standard one-letter amino acid codes, wherein X is any amino acid residue) is as follows.

-G-X₅-G-X₂-E-X₆-W-G-X₂-C-X₃-(F or Y or W)-X₈-C-X₃-G- (SEQ ID NO: 456).

5 Speract is a transmembrane glycoprotein of 500 amino acid residues (Dangott et al. (1989) Proc. Natl. Acad. Sci. USA 86:2128-2132). Structurally, this receptor consists of a large extracellular domain of 450 residues, followed by a transmembrane region and a small cytoplasmic domain of 12 amino acid residues. The extracellular domain contains four repeats of an approximately 115 amino acid domain. There are
10 17 amino acid residues that are perfectly conserved in the four repeats in speract, including six cysteine residues, six glycine residues, and two glutamate residues. TANGO 234 has five SRR domains, in which 16 of the 17 conserved speract residues are present of four of the SRR domains and 15 are present in the remaining SRR domain. This domain is designated the speract receptor repeated domain. The amino
15 acid sequence of mammalian macrophage scavenger receptor type I (MSRI) exhibits such a domain (Freeman et al. (1990) Proc. Natl. Acad. Sci. USA 87:8810-8814). MSRI proteins are membrane glycoproteins implicated in the pathologic deposition of cholesterol in arterial walls during atherogenesis. TANGO 234 is involved in one or more physiological processes related to cholesterol deposition and atherogenesis, as
20 well as other vascular and cardiovascular disorders.

Scavenger receptor cysteine-rich (SRCR) domains are disulfide rich extracellular domains which are present in certain cell surface and secreted proteins. Proteins having SRCR domains exhibit diverse ligand binding specificity. For example, in addition to modified lipoproteins, some of these proteins bind a variety of
25 surface components of pathogenic microorganisms, and some of the proteins bind apoptotic cells. SRCR domains are also involved in mediating immune development and response. Other SRCR-containing proteins are involved in binding of modified lipoproteins (e.g., oxidized low density lipoprotein {LDL}) by specialized

macrophages, leading to the formation of macrophages filled with cholesteryl ester droplets (i.e., foam cells). TANGO 234 is involved in one or more physiological processes in which these other SRCR domain-containing proteins are involved, such as LDL uptake and metabolism, regulation of serum cholesterol level, atherogenesis, atherosclerosis, bacterial or viral infections, immune development, and generation and perseverance of immune responses.

WC1 is a ruminant protein having an SRCR domain. WC1 and gamma delta T-cell receptor are the only known gamma delta T-cell specific antigens. Antibodies which bind specifically with WC1 induce growth arrest in IL-2-dependent gamma delta T-cell and augment proliferation of gamma delta T-cells in an autologous mixed lymphocyte reaction or in the presence of anti-CD2 or anti-CD5 antibodies. Injection of antibodies which bind specifically with WC1 into calves results in long-lasting depletion of gamma delta T-cells. Furthermore, antibodies which bind specifically with WC1 can be used to purify gamma delta T-cells.

Gamma delta T-cells are involved in a variety of physiological processes. For example, these cells are potential mediators of allergic airway inflammation and lyme disease. Furthermore, these cells are involved in natural resistance to viral infections and can mediate autoimmune diseases. Elimination of gamma delta T-cells by injection of antibodies which bind specifically therewith can affect the outcomes of these disorders.

TANGO 234 is likely the human orthologue of ruminant protein WC1, and thus is involved with the physiological processes described above in humans. An alignment of the amino acid sequences of (human) TANGO 234 and bovine WC1 protein is shown in Figures 26K-26P. In this alignment (made using the ALIGN software {Myers and Miller (1989) CABIOS, ver. 2.0}; pam120.mat scoring matrix; gap penalties -12/-4), the proteins are 40.4% identical. An alignment of the nucleotide sequences of the ORFs encoding (human) TANGO 234 and bovine WC1 protein is

shown in Figures 26Q-1 to 26Q-19. The two ORFs are 54.3% identical, as assessed using the same software and parameters.

The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that human TANGO 234 protein includes a 40 amino acid signal peptide (amino acid residues 1 to 40 of SEQ ID NO: 381; SEQ ID NO: 382) preceding the mature TANGO 234 protein (amino acid residues 41 to 4386 of SEQ ID NO: 381; SEQ ID NO: 383). Human TANGO 234 protein includes an extracellular domain (amino acid residues 41 to 1359 of SEQ ID NO: 381; SEQ ID NO: 384); a transmembrane domain (amino acid residues 1360 to 1383 of SEQ ID NO: 381; SEQ ID NO: 385); and a cytoplasmic domain (amino acid residues 1384 to 1453 of SEQ ID NO: 381; SEQ ID NO: 386).

Figure 26J depicts a hydrophobicity plot of human TANGO 234 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to 40 of SEQ ID NO: 381 is the signal sequence of human TANGO 234 (SEQ ID NO: 382). The hydrophobic region which corresponds to amino acid residues 1360 to 1383 of SEQ ID NO: 381 is the transmembrane domain of human TANGO 234 (SEQ ID NO: 385). As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human TANGO 234 protein from about amino acid residue 225 to about amino acid residue 250 appears to be located at or near the surface of the protein, while the region from about amino acid residue 990 to about amino acid residue 1000 appears not to be located at or near the surface.

The predicted molecular weight of human TANGO 234 protein without modification and prior to cleavage of the signal sequence is about 159.3 kilodaltons.

The predicted molecular weight of the mature human TANGO 234 protein without modification and after cleavage of the signal sequence is about 154.7 kilodaltons.

Chromosomal mapping to identify the location of the gene encoding human TANGO 234 protein indicated that the gene was located at chromosomal location
5 h12p13 (with synteny to mo6). Flanking chromosomal markers include WI-6980 and GATA8A09.43. Nearby human loci include IBD2 (inflammatory bowel disease 2), FPF (familial periodic fever), and HPDR2 (hypophosphatemia vitamin D resistant rickets 2). Nearby genes are KLRC (killer cell receptor cluster), DRPLA (dentatorubro-pallidoluysian atrophy), GAPD (glyceraldehyde-3-phosphate)
10 dehydrogenase, and PXR1 (peroxisome receptor 1). Murine chromosomal mapping indicated that the murine orthologue is located near the scr (scruffy) locus. Nearby mouse genes include drpla (dentatorubral phillidolusian atrophy), prp (proline rich protein), and kap (kidney androgen regulated protein).

Northern analysis experiments indicated that mRNA corresponding to the
15 cDNA encoding TANGO 234 is expressed in the tissues listed in Table XXVIII, wherein "++" indicates moderate expression, "+" indicates lower expression, and "-" indicates no detectable expression.

Table XXVIII

Animal	Tissue	Relative Level of Expression
Human	spleen	++
	fetal lung	++
	lung	+
	thymus	+
	bone marrow	-
	peripheral blood leukocytes	-

Uses of TANGO 234 Nucleic acids,
Polypeptides, and Modulators Thereof

TANGO 234 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not
5 expressed. Based on the observation that TANGO 234 is expressed in human fetal lung, spleen, and, to a lesser extent in adult lung and thymus tissue, TANGO 234 protein is involved in one or more biological processes which occur in these tissues. In particular, TANGO 234 is involved in modulating growth, proliferation, survival, differentiation, and activity of cells including, lung, spleen, thymus, bone marrow,
10 hematopoietic, peripheral blood leukocytes, and fetal cells of the animal in which it is normally expressed. Thus, TANGO 234 has a role in disorders which affect these cells and their growth, proliferation, survival, differentiation, and activity. TANGO 234 can have a role in the lung, spleen, and hematological described elsewhere in this disclosure. Expression of TANGO 234 in an animal is also involved in modulating
15 growth, proliferation, survival, differentiation, and activity of cells and viruses which are foreign to the host (i.e., bacterial, fungal, and viral infections).

Homology of human TANGO 234 with bovine WC1 protein indicates that TANGO 234 has physiological functions in humans analogous to the functions of WC1 in ruminants. Thus, TANGO 234 is involved in modulating growth, proliferation,
20 survival, differentiation, and activity of gamma delta T cells. For example, TANGO 234 affects the ability of gamma delta T cells to interact with chemokines such as interleukin-2. TANGO 234 therefore is involved in the physiological processes associated with allergic airway inflammation, lyme arthritis, resistance to viral infection, auto-immune diseases, and the like.

25 In addition, presence in TANGO 234 of SRR and SRCR domains indicates that TANGO 234 is involved in physiological functions identical or analogous to the functions performed by other proteins having such domains. For example, like other SRR domain-containing proteins, TANGO 234 modulates cholesterol deposition in

arterial walls, and is thus involved in development and persistence of atherogenesis and arteriosclerosis, as well as other vascular and cardiovascular disorders. Like other SRCR domain-containing proteins, TANGO 234 is involved in uptake and metabolism of LDL, regulation of serum cholesterol level, and can modulate these processes as well as the processes of atherogenesis, arteriosclerosis, immune development, and generation and perseverance of immune responses to bacterial, fungal, and viral infections.

TANGO 265

10 A cDNA clone (designated jthsa079g01) encoding at least a portion of human TANGO 265 protein was isolated from a human fetal spleen cDNA library. The human TANGO 265 protein is predicted by structural analysis to be a transmembrane membrane protein, although it can exist in a secreted form as well.

15 The full length of the cDNA encoding human TANGO 265 protein (Figure 27; SEQ ID NO: 387) is 3104 nucleotide residues. The ORF of this cDNA, nucleotide residues 32 to 2314 of SEQ ID NO: 387 (i.e., SEQ ID NO: 388), encodes a 761-amino acid transmembrane protein (Figure 27; SEQ ID NO: 389).

20 The invention thus includes purified TANGO 265 protein, both in the form of the immature 761 amino acid residue protein (SEQ ID NO: 389) and in the form of the mature 730 amino acid residue protein (SEQ ID NO: 391). Mature TANGO 265 protein can be synthesized without the signal sequence polypeptide at the amino terminus thereof, or it can be synthesized by generating immature TANGO 265 protein and cleaving the signal sequence therefrom.

25 The invention includes nucleic acid molecules which encode a polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the nucleotide sequence listed in SEQ ID NO: 387 or some portion thereof, such as the portion which encodes mature TANGO 265 protein, immature TANGO 265 protein, or

a domain of TANGO 265 protein. These nucleic acids are collectively referred to as nucleic acids of the invention.

TANGO 265 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional features.

5 A common domain present in TANGO 265 proteins is a signal sequence. In one embodiment, a TANGO 265 protein contains a signal sequence corresponding to amino acid residues 1 to 31 of SEQ ID NO: 389 (SEQ ID NO: 390). The signal sequence is cleaved during processing of the mature protein.

10 TANGO 265 proteins can also include an extracellular domain. The human TANGO 265 protein extracellular domain is located from about amino acid residue 32 to about amino acid residue 683 of SEQ ID NO: 389. TANGO 265 can alternately exist in a secreted form, such as a mature protein having the amino acid sequence of amino acid residues 32 to 761 or residues 32 to about 683 of SEQ ID NO: 389.

15 TANGO 265 proteins can also include a transmembrane domain. In one embodiment, a TANGO 265 protein of the invention contains a transmembrane domain corresponding to about amino acid residues 684 to 704 of SEQ ID NO: 389 (SEQ ID NO: 393).

20 In addition, TANGO 265 proteins include a cytoplasmic domain, particularly including proteins having a carboxyl-terminal cytoplasmic domain. The human TANGO 265 cytoplasmic domain is located from about amino acid residue 705 to amino acid residue 761 of SEQ ID NO: 389 (SEQ ID NO: 394).

25 TANGO 265 proteins typically comprise a variety of potential post-translational modification sites (often within an extracellular domain), such as those described herein in Table XXIX, as predicted by computerized sequence analysis of TANGO 265 proteins using amino acid sequence comparison software (comparing the amino acid sequence of TANGO 265 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}). In

certain embodiments, a protein of the invention has at least 1, 2, 4, 6, 10, 15, or 20 or more of the post-translational modification sites listed in Table XXIX.

Table XXIX

	437 to 442	GTTTGS
	620 to 625	GLYQCW
Sema domain	671 to 676	GAALAA
	64 to 478	See Fig. 27

5 An example of a domain which occurs in TANGO 265 proteins is a sema domain. In one embodiment, the protein of the invention has at least one domain that is at least 55%, preferably at least about 65%, more preferably at least about 75%, yet more preferably at least about 85%, and most preferably at least about 95% identical to one of the sema domains described herein in Table XXIX.

10 Sema domains occur in semaphorin proteins. Semaphorins are a large family of secreted and transmembrane proteins, some of which function as repellent signals during neural axon guidance. The sema domain and a variety of semaphorin proteins

in which it occurs are described, for example, in Winberg et al. (1998 Cell 95:903-916). Sema domains also occur in human hepatocyte growth factor receptor (Swissprot Accession no. P08581) and the similar neuronal and epithelial transmembrane receptor protein (Swissprot Accession no. P51805). The presence of an sema domain in human
5 TANGO 265 protein indicates that TANGO 265 is involved in one or more physiological processes in which the semaphorins are involved, has biological activity in common with one or more of the semaphorins, or both.

Human TANGO 265 protein exhibits considerable sequence similarity to murine semaphorin B protein (GenBank Accession no. X85991), as indicated herein in
10 Figures 27F to 27H. Figures 27F to 27H depict an alignment of the amino acid sequences of human TANGO 265 protein (SEQ ID NO: 389) and murine semaphorin B protein (SEQ ID NO: 446). In this alignment (pam120.mat scoring matrix, gap penalties -12/-4), the amino acid sequences of the proteins are 82.3% identical. Figures 27I through 27T depict an alignment of the nucleotide sequences of cDNA encoding
15 human TANGO 265 protein (SEQ ID NO: 387) and murine cDNA encoding semaphorin B protein (SEQ ID NO: 447). In this alignment (pam120.mat scoring matrix, gap penalties -12/-4), the nucleic acid sequences of the cDNAs are 76.2% identical. Thus, TANGO 265 is the human orthologue of murine semaphorin B and shares functional similarities to that protein.

20 It is known that semaphorins are bi-functional, capable of functioning either as attractive axonal guidance proteins or as repellent axonal guidance proteins (Wong et al. (1997) Development 124:3597-3607). Furthermore, semaphorins bind with neuronal cell surface proteins designated plexins, which are expressed on both neuronal cells and cells of the immune system (Comeau et al. (1998) Immunity 8:473-482; Jin
25 and Strittmatter (1997) J. Neurosci. 17:6256-6263).

The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that human TANGO 265 protein includes a 31 amino acid signal peptide (amino acid residues 1 to 31 of SEQ ID NO: 389; SEQ ID NO: 390)

preceding the mature TANGO 265 protein (amino acid residues 32 to 761 of SEQ ID NO: 389; SEQ ID NO: 391). Human TANGO 265 protein includes an extracellular domain (amino acid residues 32 to 683 of SEQ ID NO:389; SEQ ID NO: 392); a transmembrane domain (amino acid residues 684 to 704 of SEQ ID NO: 389; SEQ ID NO: 393); and a cytoplasmic domain (amino acid residues 705 to 761 of SEQ ID NO: 389; SEQ ID NO: 394).

Figure 27U depicts a hydrophobicity plot of human TANGO 265 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to 31 of SEQ ID NO: 389 is the signal sequence of human TANGO 265 (SEQ ID NO: 390). The hydrophobic region which corresponds to amino acid residues 684 to 704 of SEQ ID NO: 389 is the transmembrane domain of human TANGO 265 (SEQ ID NO: 393). As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human TANGO 265 protein from about amino acid residue 350 to about amino acid residue 375 appears to be located at or near the surface of the protein, while the region from about amino acid residue 230 to about amino acid residue 250 appears not to be located at or near the surface.

The predicted molecular weight of human TANGO 265 protein without modification and prior to cleavage of the signal sequence is about 83.6 kilodaltons. The predicted molecular weight of the mature human TANGO 265 protein without modification and after cleavage of the signal sequence is about 80.2 kilodaltons.

Chromosomal mapping was performed by computerized comparison of TANGO 265 cDNA sequences against a chromosomal mapping database in order to identify the approximate location of the gene encoding human TANGO 265 protein.

This analysis indicated that the gene was located on chromosome 1 between markers D1S305 and D1S2635.

Uses of TANGO 265 Nucleic acids,
5 Polypeptides, and Modulators Thereof

TANGO 265 proteins are involved in disorders which affect both tissues in which they are normally expressed and tissues in which they are normally not expressed. Based on the observation that TANGO 265 is expressed in human fetal spleen, involvement of TANGO 265 protein in immune system development and
10 modulation is indicated.

The presence of the sema domain in TANGO 265 indicates that this protein is involved in development of neuronal and epithelial tissues and also functions as a repellant protein which guides axonal development. TANGO 265 modulates nerve growth and regeneration and also modulates growth and regeneration of other epithelial
15 tissues.

TANGO 265 nucleic acids, proteins, and modulators thereof can be used to modulate proliferation, migration, morphology, differentiation, function, or some combination of these, of cells that form the spleen, (e.g., cells of the splenic connective tissue, splenic smooth muscle cells, or endothelial cells of the splenic blood vessels) or
20 of blood cells that are processed (e.g., regenerated, matured, or phagocytized) within the spleen, as described elsewhere in this disclosure.

The observation that TANGO 265 shares significant identity with murine semaphorin B suggests that it has activity identical or analogous to the activity of this protein. These observations indicate that TANGO 265 modulates growth,
25 proliferation, survival, differentiation, and activity of neuronal cells and immune system cells. Thus, TANGO 265 protein is useful, for example, for guiding neural axon development, for modulating differentiation of cells of the immune system, for modulating cytokine production by cells of the immune system, for modulating

reactivity of cells of the immune system toward cytokines, for modulating initiation and persistence of an inflammatory response, and for modulating proliferation of epithelial cells.

5 TANGO 286

A cDNA clone (designated jthkf042e03) encoding at least a portion of human TANGO 286 protein was isolated from a human keratinocyte cDNA library. The human TANGO 286 protein is predicted by structural analysis to be a secreted protein.

10 The full length of the cDNA encoding TANGO 286 protein (Figure 28; SEQ ID NO: 403) is 1980 nucleotide residues. The ORF of this cDNA, nucleotide residues 133 to 1497 of SEQ ID NO: 403 (i.e., SEQ ID NO: 404), encodes a 455-amino acid secreted protein (Figure 28; SEQ ID NO: 405).

15 The invention thus includes purified TANGO 286 protein, both in the form of the immature 455 amino acid residue protein (SEQ ID NO: 405) and in the form of the mature 432 amino acid residue protein (SEQ ID NO: 407). Mature TANGO 286 protein can be synthesized without the signal sequence polypeptide at the amino terminus thereof, or it can be synthesized by generating immature TANGO 286 protein and cleaving the signal sequence therefrom.

20 The invention includes nucleic acid molecules which encode a polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the nucleotide sequence listed in SEQ ID NO: 403 or some portion thereof, such as the portion which encodes mature TANGO 286 protein, immature TANGO 286 protein, or a domain of TANGO 286 protein. These nucleic acids are collectively referred to as nucleic acids of the invention.

25 TANGO 286 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional features.

A common domain of TANGO 286 proteins is a signal sequence. In one embodiment, a TANGO 286 protein contains a signal sequence corresponding to

amino acid residues 1 to 23 of SEQ ID NO: 405 (SEQ ID NO: 406). The signal sequence is cleaved during processing of the mature protein.

TANGO 286 is a secreted soluble protein (i.e., a secreted protein having a single extracellular domain), as indicated by computerized sequence analysis and comparison of the amino acid sequence of TANGO 286 with related proteins, such as the soluble proteins designated bactericidal permeability increasing (BPI) protein and recombinant endotoxin neutralizing polypeptide (RENK).

TANGO 286 proteins typically comprise a variety of potential post-translational modification sites (often within an extracellular domain), such as those described herein in Table XXX, as predicted by computerized sequence analysis of TANGO 286 proteins using amino acid sequence comparison software (comparing the amino acid sequence of TANGO 286 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}). In certain embodiments, a protein of the invention has at least 1, 2, 4, 6, 10, 15, or 20 or more of the post-translational modification sites listed in Table XXX.

Table XXX

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 405	Amino Acid Sequence
N-glycosylation site	79 to 82	NFSN
	92 to 95	NTSL
	113 to 116	NIST
	161 to 164	NLST
	173 to 176	NYTL
	205 to 208	NLTD
	249 to 252	NLTL
	303 to 306	NFTL
	320 to 323	NSTV
	363 to 366	NRSN

Table XXX (Continued)

Protein kinase C phosphorylation site	35 to 37	TQR
	362 to 364	SNR
	429 to 431	SSK
Casein kinase II phosphorylation site	63 to 66	SGSE
	130 to 133	SFAE
	163 to 166	STLE
	169 to 172	TKID
	175 to 178	TLLD
	183 to 186	SSPE

N-myristoylation site	42 to 47	GVQAGM
	269 to 274	GNVLSR
Lipid-binding serum glycoprotein domain	12 to 427	see Fig. 28

Certain lipid-binding serum glycoproteins, such as LPS-binding protein (LBP), bactericidal permeability-increasing protein (BPI), cholesteryl ester transfer protein (CETP), and phospholipid transfer protein (PLTP), share regions of sequence similarity which are herein designated a lipid-binding serum glycoprotein domain (Schumann et al., (1990) Science 249:1429-1431; Gray et al., (1989) J. Biol. Chem. 264:9505-9509; Day et al., (1994) J. Biol. Chem. 269:9388-9391). The consensus pattern of lipid-binding serum glycoprotein domains is as follows (using standard single letter amino acid abbreviations wherein X is any amino acid residue).

- (P or A) - (G or A) - (L or I or V or M or C) - X₂ - R - (I or V) - (S or T) -
X₃ - L - X_(4 or 5) - (E or Q) - X₄ - (L or I or V or M) - X_(0 or 1) - (E or Q or K) - X₈ - P -
(SEQ ID NO: 457; e.g., amino acid residues 28-60 of SEQ ID NO: 405).

Proteins in which a lipid-binding serum glycoprotein domain occurs are often
5 structurally related and exhibit related physiological activities. LBP binds to lipid A moieties
of bacterial LPS and, once bound thereto, induces secretion of α -tumor necrosis factor,
apparently by interacting with the CD14 receptor. BPI also binds LPS and exerts a cytotoxic
effect on Gram-negative bacteria (Elsbach, (1998) J. Leukoc. Biol. 64:14-18). CETP is
involved in transfer of insoluble cholesteryl esters during reverse cholesterol transport. PLTP
10 appears to be involved in phospholipid transport and modulation of serum HDL particles.

The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein
Engineering 10:1-6) predicted that TANGO 286 protein includes a 23 amino acid signal
peptide (amino acid residues 1 to 23 of SEQ ID NO: 405; SEQ ID NO: 406) preceding the
mature TANGO 286 protein (amino acid residues 24 to 455 of SEQ ID NO: 45; SEQ ID NO:
15 407). Human TANGO 286 protein is a secreted soluble protein.

Figure 28E depicts a hydrophobicity plot of TANGO 286 protein. Relatively
hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions
are below the dashed horizontal line. As described elsewhere herein, relatively hydrophilic
regions are generally located at or near the surface of a protein, and are more frequently
20 effective immunogenic epitopes than are relatively hydrophobic regions. For example, the
region of human TANGO 286 protein from about amino acid residue 420 to about amino acid
residue 435 appears to be located at or near the surface of the protein, while the region from
about amino acid residue 325 to about amino acid residue 345 appears not to be located at or
near the surface.

25 The predicted molecular weight of TANGO 286 protein without modification and prior
to cleavage of the signal sequence is about 50.9 kilodaltons. The predicted molecular weight of
the mature TANGO 286 protein without modification and after cleavage of the signal sequence
is about 48.2 kilodaltons.

The gene encoding human TANGO 286 protein was determined to be located on chromosome 22 by comparison of matching genomic clones such as the clones assigned GenBank Accession numbers W16806 and AL021937.

A portion of TANGO 286 protein exhibits significant amino acid homology with a region of the human chromosome region 22q12-13 genomic nucleotide sequence having GenBank Accession number AL021937. Alignment of a 45 kilobase nucleotide sequence encoding TANGO 286 with AL021937, however, indicated the presence in TANGO 286 of exons which differ from those disclosed in L021937 (pam120.mat scoring matrix; gap penalties -12/-4). This region of chromosome 22 comprises an immunoglobulin lambda chain C (IGLC) pseudogene, the Ret finger protein-like 3 (RFPL3) and Ret finger protein-like 3 antisense (RFPL3S) genes, a gene encoding a novel immunoglobulin lambda chain V family protein, a novel gene encoding a protein similar both to mouse RGDS protein (RALGDS, RALGEF, guanine nucleotide dissociation stimulator A) and to rabbit oncogene RSC, a novel gene encoding the human orthologue of worm F16A11.2 protein, a novel gene encoding a protein similar both to BPI and to rabbit liposaccharide-binding protein, and a 5'-portion of a novel gene. This region also comprises various ESTs, STSs, GSSs, genomic marker D22S1175, a ca repeat polymorphism and putative CpG islands. TANGO 286 protein thus shares one or more structural or functional features of these molecules.

TANGO 286 protein exhibits considerable sequence similarity with BPI protein, having 23.9% amino acid sequence identity therewith, as assessed using the ALIGN v. 2.0 computer software using a pam120.mat scoring matrix and gap penalties of -12/-4. TANGO 286 protein also exhibits considerable sequence similarity with recombinant endotoxin neutralizing polypeptide (RENP), having 24.5% amino acid sequence identity therewith, as assessed using the ALIGN software. Physiological activities of BPI protein and RENP have been described (e.g., Gabay et al., (1989) Proc. Natl. Acad. Sci. USA 86:5610-5614; Elsbach, (1998) J. Leukoc. Biol. 64:14-18; Mahadeva et al., (1997) Chest 112:1699-1701; International patent application WO96/34873). RENP, for example, binds LPS and neutralizes bacterial endotoxins. BPI, RENP, and other proteins in which a lipid-binding serum glycoprotein

domain occurs bind LPS and neutralize bacterial endotoxins, and are therefore useful for preventing, detecting, and treating LPS-related disorders such as shock, disseminated intravascular coagulation, anemia, thrombocytopenia, adult respiratory distress syndrome, renal failure, liver disease, and disorders associated with Gram negative bacterial infections. In addition to the physiological conditions described above, BPI protein is known to be involved in vasculitis and bronchiectasis, in that antibodies which bind specifically with BPI protein are present in at least some patients afflicted with these disorders (Mahadeva et al., supra).

Uses of TANGO 286 Nucleic acids,

Polypeptides, and Modulators Thereof

Expression of TANGO 286 in keratinocyte library indicates that this protein is involved in a disorders which involve keratinocytes. Such disorders include, for example, disorders involving extracellular matrix abnormalities, dermatological disorders, ocular disorders, inappropriate hair growth (e.g., baldness), infections of the nails of the fingers and toes, scalp disorders (e.g., dandruff), and the like.

The fact that TANGO 286 protein contains a lipid-binding serum glycoprotein domain indicates that TANGO 286 is involved in one or more physiological processes in which these other lipid-binding serum glycoprotein domain-containing proteins are involved. Thus, TANGO 286 is involved in one or more of lipid transport, metabolism, serum lipid particle regulation, host anti-microbial defensive mechanisms, and the like.

Human TANGO 286 shares physiological functionality with other proteins in which a lipid-binding serum glycoprotein domains occurs (e.g., LBP, BPI protein, CETP, and PLTP). Based on the amino acid sequence similarity of TANGO 286 with BPI protein and with RENP, TANGO 286 protein exhibits physiological activities exhibited by these proteins. Thus, TANGO 286 proteins are useful for preventing, diagnosing, and treating, among others, lipid transport disorders, lipid metabolism disorders, disorders of serum lipid particle regulation, obesity, disorders involving insufficient or inappropriate host anti-microbial defensive mechanisms, vasculitis, bronchiectasis, LPS-related disorders such as shock, disseminated

intravascular coagulation, anemia, thrombocytopenia, adult respiratory distress syndrome, renal failure, liver disease, and disorders associated with Gram negative bacterial infections, such as bacteremia, endotoxemia, sepsis, and the like.

5 TANGO 294

A cDNA clone (designated jthrc145g07) encoding at least a portion of human TANGO 294 protein was isolated from a human pulmonary artery smooth muscle cell cDNA library. The human TANGO 294 protein is predicted by structural analysis to be a transmembrane membrane protein. No expression of DNA encoding TANGO 294 was detected in human
10 heart, brain, placenta, lung, liver, skeletal muscle, kidney, or pancreas tissues.

The full length of the cDNA encoding TANGO 294 protein (Figure 29; SEQ ID NO: 415) is 2044 nucleotide residues. The ORF of this cDNA, nucleotide residues 126 to 1394 of SEQ ID NO: 415 (i.e., SEQ ID NO: 416), encodes a 423-amino acid transmembrane protein (Figure 29; SEQ ID NO: 417).

15 The invention includes purified TANGO 294 protein, both in the form of the immature 423 amino acid residue protein (SEQ ID NO: 417) and in the form of the mature 390 amino acid residue protein (SEQ ID NO: 419). Mature TANGO 294 protein can be synthesized without the signal sequence polypeptide at the amino terminus thereof, or it can be synthesized by generating immature TANGO 294 protein and cleaving the signal sequence therefrom.

20 The invention includes nucleic acid molecules which encode a polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the nucleotide sequence listed in SEQ ID NO: 415 or some portion thereof, such as the portion which encodes mature TANGO 294 protein, immature TANGO 294 protein, or a domain of TANGO 294 protein. These nucleic acids are collectively referred to as nucleic acids of the invention.

25 TANGO 294 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional features.

Also included within the scope of the invention are TANGO 294 proteins having a signal sequence. In one embodiment, a TANGO 294 protein contains a signal sequence

corresponding to amino acid residues 1 to 33 of SEQ ID NO: 417 (SEQ ID NO: 418). The signal sequence is cleaved during processing of the mature protein.

The naturally-occurring form of TANGO 294 protein is a secreted protein (i.e., not comprising the predicted signal sequence). However, in variant forms, TANGO 294 proteins can be transmembrane proteins which include an extracellular domain. In this transmembrane variant form, the predicted TANGO 294 protein extracellular domain is located from about amino acid residue 34 to about amino acid residue 254 of SEQ ID NO: 417, the predicted cytoplasmic domain is located from about amino acid residue 280 to amino acid residue 423 of SEQ ID NO: 417 (SEQ ID NO: 422), and the predicted transmembrane domain is located from about amino acid residues 255 to 279 of SEQ ID NO: 417 (SEQ ID NO: 421).

TANGO 294 proteins typically comprise a variety of potential post-translational modification sites (often within an extracellular domain), such as those described herein in Table XXXI, as predicted by computerized sequence analysis of TANGO 294 proteins using amino acid sequence comparison software (comparing the amino acid sequence of TANGO 294 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}). In certain embodiments, a protein of the invention has at least 1, 2, 4, 6, 10, 15, or 20 or more of the post-translational modification sites listed in Table XXXI.

Table XXXI

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 417	Amino Acid Sequence
N-glycosylation site	48 to 51	NISE
	113 to 116	NNSL
	285 to 288	NMSR
	413 to 416	NLSQ
Protein kinase C phosphorylation site	12 to 14	SHR
	138 to 140	SRK
	217 to 219	TVK

Table XXXI (Continued)

Casein kinase II phosphorylation site	155 to 158	SYDE
	175 to 178	TGQE
	198 to 201	TMPE
	360 to 363	SNPE
Tyrosine kinase phosphorylation site	174 to 182	KTGQEKIYY
N-myristoylation site	99 to 104	GLVGGA
	130 to 135	GNSRGN
	188 to 193	GTTMGF
	277 to 282	GGFNTN
Amidation site	240 to 243	FGKK
Lipase serine active site	180 to 189	IYYVGYSQGT
Alpha/beta hydrolase fold domain	125 to 404	See Fig. 29

Alpha/beta hydrolase fold domains occur in a wide variety of enzymes (Ollis et al., (1992) Protein Eng. 5:197-211). The alpha/beta fold domain is a conserved topological domain in which sequence homology is not necessarily conserved. Conservation of topology in the alpha/beta fold domain preserves arrangement of catalytic residues, even though those residues, and the reactions they catalyze, can vary. In many enzymes, particularly including alpha/beta hydrolases, this domain encompasses the active site of the enzyme. In one embodiment, the protein of the invention has at least one domain that is at least 55%, preferably at least about 65%, more preferably at least about 75%, yet more preferably at least about 85%, and most preferably at least about 95% identical to the alpha/beta hydrolase fold domain described herein in Table XXXI.

The signal peptide prediction program SIGNALP (Nielsen et al. (1997) Protein Engineering 10:1-6) predicted that human TANGO 294 protein includes a 33 amino acid signal peptide (amino acid residues 1 to 33 of SEQ ID NO: 417; SEQ ID NO: 418) preceding the

5 mature TANGO 294 protein (amino acid residues 34 to 423 of SEQ ID NO: 417; SEQ ID NO: 419). Human TANGO 294 protein is a soluble secreted protein. However, in the transmembrane variant form, human TANGO 294 protein includes an extracellular domain (amino acid residues 34 to 254 of SEQ ID NO: 417; SEQ ID NO: 420); a transmembrane domain (amino acid residues 255 to 279 of SEQ ID NO: 417; SEQ ID NO: 421); and a cytoplasmic domain (amino acid residues 280 to 423 of SEQ ID NO: 417; SEQ ID NO: 422).

10 Figure 29F depicts a hydrophobicity plot of human TANGO 294 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic region which corresponds to amino acid residues 1 to 33 of SEQ ID NO: 417 is the signal sequence of human TANGO 294 (SEQ ID NO: 419). The hydrophobic region which corresponds to amino acid residues 255 to 279 of SEQ ID NO: 417 is the predicted transmembrane domain of human TANGO 294 (SEQ ID NO: 421). As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human TANGO 294 protein from about amino acid residue 130 to about amino acid residue 150 appears to be located at or near the surface of the protein, while the region from about amino acid residue 90 to about amino acid residue 100 appears not to be located at or near the surface.

20 The predicted molecular weight of human TANGO 294 protein without modification and prior to cleavage of the signal sequence is about 48.2 kilodaltons. The predicted molecular weight of the mature human TANGO 294 protein without modification and after cleavage of the signal sequence is about 44.2 kilodaltons.

25 It may be that amino acid residues 1 to 15 of SEQ ID NO: 417 do not occur in TANGO 294 protein. However, it is recognized that amino acid residues 16 to 33 of SEQ ID NO: 417 form a functional signal sequence even in the absence of residues 1 to 15. The amino acid sequence (and hence the properties) of mature TANGO 294 protein are unaffected by presence or absence of amino acid residues 1 to 15 of immature TANGO 294 protein.

Human TANGO 294 protein exhibits considerable sequence similarity (i.e., about 75% amino acid sequence identity) to lingual and gastric lipase proteins of rat (Swissprot Accession no. P04634; Docherty et al. (1985) *Nucleic Acids Res.* 13:1891-1903), dog (Swissprot Accession no. P80035; Carriere et al. (1991) *Eur. J. Biochem.* 202:75-83), and human
5 (Swissprot Accession no. P07098; Bernbaeck and Blaeckberg (1987) *Biochim. Biophys. Acta* 909:237-244), as assessed using the ALIGN v. 2.0 computer software using a pam12.mat scoring matrix and gap penalties of -12/-4. TANGO 294 is distinct from the known human lipase, as indicated in Figures 29D and 29E. Figures 29D and 29E depict an alignment of the amino acid sequences of human TANGO 294 protein (SEQ ID NO: 417) and the known human
10 lipase protein (SEQ ID NO: 445), as assessed using the same software and parameters. In this alignment (pam120.mat scoring matrix, gap penalties -12/-4), the amino acid sequences of the proteins are 49.8% identical. TANGO 294 also is distinct from the known human lysosomal acid lipase, as indicated in Figures 29G and 29H. Figures 29G and 29H depicts an alignment of the amino acid sequences of human TANGO 294 protein (SEQ ID NO: 417) and the known
15 human lysosomal acid lipase protein (SEQ ID NO: 411). In this alignment (pam120.mat scoring matrix, gap penalties -12/-4), the amino acid sequences of the proteins are 56.9% identical.

TANGO 294 is a human lipase distinct from the known human lipase and the known human lysosomal acid lipase. Furthermore, in view of the comparisons of the amino acid
20 sequences of TANGO 294 and the two human lipases and the nature of transcriptional initiation sites, it is recognized that the transcriptional start site can correspond to either of the methionine residues located at residues 1 and 15 of SEQ ID NO: 417. The present invention thus includes proteins in which the initially transcribed amino acid residue is the methionine residue at position 1 of SEQ ID NO: 417 and proteins in which the initially transcribed amino
25 acid residue is the methionine residue at position 15 of SEQ ID NO: 417 (i.e., proteins in which the amino acid sequence of TANGO 294 does not include residues 1 to 14 of SEQ ID NO: 417). Furthermore, because amino acid residues 1 to 14 of SEQ ID NO: 417 are predicted to be part of a signal sequence, it is recognized that the protein not comprising this portion of the

amino acid sequence will nonetheless exhibit a functional signal sequence at its amino terminus.

Uses of TANGO 294 Nucleic acids,
5 Polypeptides, and Modulators Thereof

The sequence similarity of TANGO 294 and mammalian lingual, gastric, and lysosomal acid lipase proteins indicates that TANGO 294 is involved in physiological processes identical or analogous to those involving these lipases. Thus, TANGO 294 is involved in facilitating absorption and metabolism of fat. TANGO 294 can thus be used, for example, to prevent,
10 detect, and treat disorders relating to fat absorption and metabolism, such as inadequate expression of gastric/pancreatic lipase, cystic fibrosis, exocrine pancreatic insufficiency, obesity, medical treatments which alter fat absorption, and the like.

TANGO 294 protein is known to be expressed in human pulmonary artery smooth muscle tissue. This indicates that TANGO 294 protein is involved in transportation and
15 metabolism of fats and lipids in the human vascular and cardiovascular systems. Thus, TANGO 294 proteins of the invention can be used to prevent, detect, and treat disorders involving these body systems.

INTERCEPT 296

20 A cDNA clone (designated jthEa030h09) encoding at least a portion of human INTERCEPT 296 protein was isolated from a human esophagus cDNA library. The human INTERCEPT 296 protein is predicted by structural analysis to be a transmembrane protein having three or more transmembrane domains. Expression of DNA encoding INTERCEPT 296 tissue has been detected by northern analysis of human lung tissue. In human lung tissue,
25 two moieties corresponding to INTERCEPT 296 have been identified in Northern blots. It is recognized that these two moieties may represent alternatively polyadenylated INTERCEPT 296 mRNAs or alternatively spliced INTERCEPT 296 mRNAs. It has furthermore been

observed that INTERCEPT 296 does not appear to be expressed in any of heart, brain, placenta, skeletal muscle, kidney, and pancreas tissues.

The full length of the cDNA encoding INTERCEPT 296 protein (Figure 30; SEQ ID NO: 423) is 2133 nucleotide residues. The ORF of this cDNA, nucleotide residues 70 to 1098 of SEQ ID NO: 423 (i.e., SEQ ID NO: 424), encodes a 343-amino acid transmembrane protein (Figure 30; SEQ ID NO: 425).

The invention includes nucleic acid molecules which encode a polypeptide of the invention. Such nucleic acids include, for example, a DNA molecule having the nucleotide sequence SEQ ID NO: 423 or some portion thereof, such as the portion which encodes INTERCEPT 296 protein or a domain thereof. These nucleic acids are collectively referred to as nucleic acids of the invention.

INTERCEPT 296 proteins and nucleic acid molecules encoding them comprise a family of molecules having certain conserved structural and functional features, such as the five transmembrane domains which occur in the protein.

INTERCEPT 296 comprises at least five transmembrane domains, at least three cytoplasmic domains, and at least two extracellular domains. INTERCEPT 296 does not appear to comprise a cleavable signal sequence. Amino acid residues 1 to 70 of SEQ ID NO: 425 likely directs insertion of the protein into the cytoplasmic membrane. There are at least two mechanisms by which this can occur. Sequence analysis of residues 1 to 70 of SEQ ID NO: 425 indicates that this entire region may represent a signal sequence or that residues 1 to 47 represent a signal sequence, with residues 48-70 representing a transmembrane region. Human INTERCEPT 296 protein extracellular domains are located from about amino acid residue 70 to about amino acid residue 182 (SEQ ID NO: 427) and from about amino acid residue 228 to about amino acid residue 249 (SEQ ID NO: 428) of SEQ ID NO: 425. Human INTERCEPT 296 cytoplasmic domains are located from about amino acid residue 43 to amino acid residue 50 (SEQ ID NO: 434), from about amino acid residue 205 to amino acid residue 210 (SEQ ID NO: 435), and from amino acid residue 272 to amino acid residue 343 (SEQ ID NO: 436) of SEQ ID NO: 425. The five transmembrane domains of INTERCEPT 296 are

located from about amino acid residues 24 to 42 (SEQ ID NO: 429), 51 to 70 (SEQ ID NO: 430), 183 to 204 (SEQ ID NO: 431), 211 to 227 (SEQ ID NO: 432), and 250 to 271 (SEQ ID NO: 433) of SEQ ID NO: 425.

INTERCEPT 296 proteins typically comprise a variety of potential post-translational modification sites (often within an extracellular domain), such as those described herein in Table XXXII, as predicted by computerized sequence analysis of INTERCEPT 296 proteins using amino acid sequence comparison software (comparing the amino acid sequence of INTERCEPT 296 with the information in the PROSITE database {rel. 12.2; Feb, 1995} and the Hidden Markov Models database {Rel. PFAM 3.3}). In certain embodiments, a protein of the invention has at least 1, 2, 4, 6, 10, 15, or 20 or more of the post-translational modification sites listed in Table XXXII.

Table XXXII

Type of Potential Modification Site or Domain	Amino Acid Residues of SEQ ID NO: 425	Amino Acid Sequence
N-glycosylation site	71 to 74	NFSS
	84 to 87	NTSY
	109 to 112	NITL
	121 to 124	NETI
	284 to 287	NQSV
Protein kinase C phosphorylation site	86 to 88	SYK
	131 to 133	TWR
	162 to 164	TPR
	304 to 306	SPR
	313 to 315	SPK
	326 to 328	STK
Casein kinase II phosphorylation site	286 to 289	SVDE
	296 to 299	SPEE
	309 to 312	SMAD

Table XXXII (Continued)

Tyrosine kinase phosphorylation site	148 to 156	KGLPDPVLY
N-myristoylation site	79 to 84	GQVSTN
	100 to 105	GLQVGL
	107 to 112	GVNITL
	265 to 270	GLAMAV

Figure 30D depicts a hydrophobicity plot of INTERCEPT 296 protein. Relatively hydrophobic regions are above the dashed horizontal line, and relatively hydrophilic regions are below the dashed horizontal line. The hydrophobic regions which corresponds to amino acid residues 24 to 42, 51 to 70, 183 to 204, 211 to 227, and 250 to 271 of SEQ ID NO: 425 are the transmembrane domains of human INTERCEPT 296 (SEQ ID NOs: 429 through 433, respectively). As described elsewhere herein, relatively hydrophilic regions are generally located at or near the surface of a protein, and are more frequently effective immunogenic epitopes than are relatively hydrophobic regions. For example, the region of human INTERCEPT 296 protein from about amino acid residue 120 to about amino acid residue 140 appears to be located at or near the surface of the protein, while the region from about amino acid residue 95 to about amino acid residue 110 appears not to be located at or near the surface.

The predicted molecular weight of INTERCEPT 296 protein without modification and prior to cleavage of the signal sequence is about 37.8 kilodaltons. The predicted molecular weight of the mature INTERCEPT 296 protein without modification and after cleavage of the signal sequence is about 30.2 kilodaltons.

Figures 30E through 30G depicts an alignment of the amino acid sequences of human INTERCEPT 296 protein (SEQ ID NO: 425) and *Caenorhabditis elegans* C06E1.3 related protein (SEQ ID NO: 410). In this alignment (pam120.mat scoring matrix, gap penalties -12/-

4), the amino acid sequences of the proteins are 26.8% identical. The *C. elegans* protein has five predicted transmembrane domains.

Uses of INTERCEPT 296 Nucleic acids,

5 Polypeptides, and Modulators Thereof

The cDNA encoding INTERCEPT 296 protein was obtained from a human esophagus cDNA library, and INTERCEPT 296 is expressed in lung tissue. The INTERCEPT 296-related proteins and nucleic acids of the invention are therefore useful for prevention, detection, and treatment of disorders of the human lung and esophagus. Examples of lung disorders in which
10 INTERCEPT 296 can be involved include the lung disorders described elsewhere in this disclosure. Examples of disorders of the esophagus in which INTERCEPT 296 can be involved include dysphagia, achalasia, heartburn, symptomatic diffuse esophageal spasm, corrosive esophagitis, candidiasis, and gastroesophageal reflux disease.

15 Tables A-1, A-2 and B-1 to B-5 summarize sequence data corresponding to the human nucleic acids and proteins disclosed herein. Tables A-3 and B-6 summarize sequence data corresponding to the non-human nucleic acids and proteins disclosed herein.

Amino Acid Residues

Notes for Tables B-1 to B-6:

¹It is recognized that the carboxyl terminal boundary of the signal sequence can be ± 1 or 2 residues from that indicated.

²It is recognized that 'extracellular' and cytoplasmic' domains can have the opposite orientation in certain embodiments, as described herein.

Various aspects of the invention are described in further detail in the following subsections.

I. Isolated Nucleic Acid Molecules

One aspect of the invention pertains to isolated nucleic acid molecules that encode a polypeptide of the invention or a biologically active portion thereof, as well as nucleic acid molecules sufficient for use as hybridization probes to identify nucleic acid molecules encoding a polypeptide of the invention and fragments of such nucleic acid molecules suitable for use as PCR primers for the amplification or mutation of nucleic acid molecules.

As used herein, the term "nucleic acid molecule" is intended to include DNA molecules (e.g., cDNA or genomic DNA) and RNA molecules (e.g., mRNA) and analogs of the DNA or RNA generated using nucleotide analogs. The nucleic acid molecule can be single-stranded or double-stranded.

An "isolated" nucleic acid molecule is one which is separated from other nucleic acid molecules which are present in the natural source of the nucleic acid molecule. Preferably, an "isolated" nucleic acid molecule is free of sequences (preferably protein-encoding sequences) which naturally flank the nucleic acid (i.e., sequences located at the 5' and 3' ends of the nucleic acid) in the genomic DNA of the organism from which the nucleic acid is derived. For example, in various embodiments, the isolated nucleic acid molecule can contain less than about 5, 4, 3, 2, 1, 0.5, or 0.1 kilobases of nucleotide sequences which naturally flank the nucleic acid molecule in genomic DNA of the cell from which the nucleic acid is derived. Moreover, an "isolated" nucleic acid molecule, such as a cDNA molecule, can be substantially free of other cellular material, or culture medium when produced by recombinant techniques, or substantially free of chemical precursors or other chemicals when chemically synthesized.

A nucleic acid molecule of the present invention, e.g., a nucleic acid molecule having the nucleotide sequence of all or a portion of any of SEQ ID NOs: 1, 2, 31, 32, 51, 52, 71, 72, 81, 82, 91, 92, 96, 97, 101, 102, 106, 107, 111, 112, 121, 122, 141, 142, 151, 152, 161, 162,

171, 172, 181, 182, 191, 192, 201, 202, 215, 217, 221, 222, 241, 242, 251, 252, 271, 272, 279, 280, 303, 304, 308, 309, 324, 325, 329, 330, 351, 352, 362, 371, 372, 379, 380, 387, 388, 403, 404, 415, 416, 423, 424, 437, 438, and the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228,

5 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764, or a complement thereof, or which has a nucleotide sequence comprising one of these sequences, can be isolated using standard molecular biology techniques and the sequence information provided herein. Using all or a portion of the nucleic acid sequences of any of SEQ ID NOs: 1, 2, 31, 32, 51, 52, 71, 72, 81, 82, 91, 92, 96,
10 97, 101, 102, 106, 107, 111, 112, 121, 122, 141, 142, 151, 152, 161, 162, 171, 172, 181, 182, 191, 192, 201, 202, 215, 217, 221, 222, 241, 242, 251, 252, 271, 272, 279, 280, 303, 304, 308, 309, 324, 325, 329, 330, 351, 352, 362, 371, 372, 379, 380, 387, 388, 403, 404, 415, 416, 423, 424, 437, 438, and the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147,
15 PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764 as a hybridization probe, nucleic acid molecules of the invention can be isolated using standard hybridization and cloning techniques (e.g., as described in Sambrook et al., Eds., Molecular Cloning: A Laboratory Manual, 2nd ed., Cold Spring Harbor Laboratory, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY, 1989).

20 A nucleic acid molecule of the invention can be amplified using cDNA, mRNA, or genomic DNA as a template and appropriate oligonucleotide primers according to standard PCR amplification techniques. The nucleic acid so amplified can be cloned into an appropriate vector and characterized by DNA sequence analysis. Furthermore, oligonucleotides corresponding to all or a portion of a nucleic acid molecule of the invention
25 can be prepared by standard synthetic techniques, e.g., using an automated DNA synthesizer.

In another embodiment, an isolated nucleic acid molecule of the invention comprises a nucleic acid molecule which is a complement of the nucleotide sequence of any of SEQ ID NOs: 1, 2, 31, 32, 51, 52, 71, 72, 81, 82, 91, 92, 96, 97, 101, 102, 106, 107, 111, 112, 121,

122, 141, 142, 151, 152, 161, 162, 171, 172, 181, 182, 191, 192, 201, 202, 215, 217, 221, 222, 241, 242, 251, 252, 271, 272, 279, 280, 303, 304, 308, 309, 324, 325, 329, 330, 351, 352, 362, 371, 372, 379, 380, 387, 388, 403, 404, 415, 416, 423, 424, 437, 438, and the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764, or a portion thereof. A nucleic acid molecule which is complementary to a given nucleotide sequence is one which is sufficiently complementary to the given nucleotide sequence that it can hybridize with the given nucleotide sequence thereby forming a stable duplex.

Moreover, a nucleic acid molecule of the invention can comprise a portion of a nucleic acid sequence encoding a full length polypeptide of the invention, such as a fragment which can be used as a probe or primer or a fragment encoding a biologically active portion of a polypeptide of the invention. The nucleotide sequence determined from cloning one gene allows generation of probes and primers designed for identifying and/or cloning homologs in other cell types, e.g., from other tissues, as well as homologs from other mammals. The probe/primer typically comprises substantially purified oligonucleotide. The oligonucleotide typically comprises a region of nucleotide sequence that hybridizes under stringent conditions with at least about 15, preferably about 25, more preferably about 40, 60, 80, 100, 150, 200, 250, 300, 350, 400, 450, 550, 650, 700, 800, 900, 1000, 1200, 1400, 1410, 1600, 1800, 2000, 2200, 2400, 2600, 2800, 3000, 3500, 4000, 4500, or 5000 or more consecutive nucleotides of the sense or anti-sense sequence of any of SEQ ID NOs: 1, 2, 31, 32, 51, 52, 71, 72, 81, 82, 91, 92, 96, 97, 101, 102, 106, 107, 111, 112, 121, 122, 141, 142, 151, 152, 161, 162, 171, 172, 181, 182, 191, 192, 201, 202, 215, 217, 221, 222, 241, 242, 251, 252, 271, 272, 279, 280, 303, 304, 308, 309, 324, 325, 329, 330, 351, 352, 362, 371, 372, 379, 380, 387, 388, 403, 404, 415, 416, 423, 424, 437, 438, and the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455,

PTA-817, PTA-1156, and PTA-1764, or of a naturally occurring mutant of any of these sequences.

Probes based on the sequence of a nucleic acid molecule of the invention can be used to detect transcripts or genomic sequences encoding the same protein molecule encoded by a selected nucleic acid molecule. The probe comprises a label group attached thereto, e.g., a radioisotope, a fluorescent compound, an enzyme, or an enzyme co-factor. Such probes can be used as part of a diagnostic test kit for identifying cells or tissues which aberrantly express the protein, such as by measuring levels of a nucleic acid molecule encoding the protein in a sample of cells from a subject, e.g., detecting mRNA levels or determining whether a gene encoding the protein has been mutated or deleted.

A nucleic acid fragment encoding a biologically active portion of a polypeptide of the invention can be prepared by isolating a portion of one of SEQ ID NOs: 2, 32, 52, 72, 82, 92, 97, 102, 107, 112, 122, 142, 152, 162, 172, 182, 192, 202, 215, 222, 242, 252, 272, 280, 304, 309, 325, 330, 352, 362, 372, 380, 388, 404, 416, 424, and 438 expressing the encoded portion of the polypeptide protein (e.g., by recombinant expression in vitro), and assessing the activity of the encoded portion of the polypeptide.

The invention further encompasses nucleic acid molecules that differ from the nucleotide sequence of any of SEQ ID NOs: 1, 2, 31, 32, 51, 52, 71, 72, 81, 82, 91, 92, 96, 97, 101, 102, 106, 107, 111, 112, 121, 122, 141, 142, 151, 152, 161, 162, 171, 172, 181, 182, 191, 192, 201, 202, 215, 217, 221, 222, 241, 242, 251, 252, 271, 272, 279, 280, 303, 304, 308, 309, 324, 325, 329, 330, 351, 352, 362, 371, 372, 379, 380, 387, 388, 403, 404, 415, 416, 423, 424, 437, 438, and the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764, due to degeneracy of the genetic code and thus encode the same protein as that encoded by the nucleotide sequence of one of SEQ ID NOs: 2, 32, 52, 72, 82, 92, 97, 102, 107, 112, 122, 142, 152, 162, 172, 182, 192, 202, 215, 222, 242, 252, 272, 280, 304, 309, 325, 330, 352, 362, 372, 380, 388, 404, 416, 424, and 438.

In addition to the nucleotide sequences of one of SEQ ID NOs: 2, 32, 52, 72, 82, 92, 97, 102, 107, 112, 122, 142, 152, 162, 172, 182, 192, 202, 215, 222, 242, 252, 272, 280, 304, 309, 325, 330, 352, 362, 372, 380, 388, 404, 416, 424, and 438, it will be appreciated by those skilled in the art that DNA sequence polymorphisms that lead to changes in the amino acid sequence can exist within a population (e.g., the human population). Such genetic polymorphisms can exist among individuals within a population due to natural allelic variation. An allele is one of a group of genes which occur alternatively at a given genetic locus.

To determine the percent identity of two amino acid sequences or of two nucleic acids, the sequences are aligned for optimal comparison purposes (e.g., gaps can be introduced in the sequence of a first amino acid or nucleic acid sequence for optimal alignment with a second amino or nucleic acid sequence). The amino acid residues or nucleotides at corresponding amino acid positions or nucleotide positions are then compared. When a position in the first sequence is occupied by the same amino acid residue or nucleotide as the corresponding position in the second sequence, then the molecules are identical at that position. The percent identity between the two sequences is a function of the number of identical positions shared by the sequences (i.e., % identity = # of identical positions / total # of positions {e.g., overlapping positions} × 100). In one embodiment, the two sequences are the same length.

The determination of percent identity between two sequences can be accomplished using a mathematical algorithm. A preferred, non-limiting example of a mathematical algorithm utilized for the comparison of two sequences is the algorithm of Karlin and Altschul (1990) Proc. Natl. Acad. Sci. USA 87:2264-2268, modified as in Karlin and Altschul (1993) Proc. Natl. Acad. Sci. USA 90:5873-5877. Such an algorithm is incorporated into the NBLAST and XBLAST programs of Altschul, et al. (1990) J. Mol. Biol. 215:403-410. BLAST nucleotide searches can be performed with the NBLAST program, score = 100, wordlength = 12 to obtain nucleotide sequences homologous to a nucleic acid molecules of the invention. BLAST protein searches can be performed with the XBLAST program, score = 50, wordlength = 3 to obtain amino acid sequences homologous to a protein molecules of the invention. To

obtain gapped alignments for comparison purposes, Gapped BLAST can be utilized as described in Altschul et al. (1997) *Nucleic Acids Res.* 25:3389-3402. Alternatively, PSI-Blast can be used to perform an iterated search which detects distant relationships between molecules (Id.). When utilizing BLAST, Gapped BLAST, and PSI-Blast programs, the default parameters of the respective programs (e.g., XBLAST and NBLAST) can be used. See <http://www.ncbi.nlm.nih.gov>.

Another preferred, non-limiting example of a mathematical algorithm utilized for the comparison of sequences is the local homology algorithm of Smith and Waterman (*Advances in Applied Mathematics* 2: 482-489 (1981)). Such an algorithm is incorporated into the BestFit program, which is part of the Wisconsin™ package, and is used to find the best segment of similarity between two sequences. BestFit reads a scoring matrix that contains values for every possible GCG symbol match. The program uses these values to construct a path matrix that represents the entire surface of comparison with a score at every position for the best possible alignment to that point. The quality score for the best alignment to any point is equal to the sum of the scoring matrix values of the matches in that alignment, less the gap creation penalty multiplied by the number of gaps in that alignment, less the gap extension penalty multiplied by the total length of all gaps in that alignment. The gap creation and gap extension penalties are set by the user. If the best path to any point has a negative value, a zero is put in that position.

After the path matrix is complete, the highest value on the surface of comparison represents the end of the best region of similarity between the sequences. The best path from this highest value backwards to the point where the values revert to zero is the alignment shown by BestFit. This alignment is the best segment of similarity between the two sequences. Further documentation can be found at <http://ir.ucdavis.edu/GCGhelp/bestfit.html#algorithm>.

Additional algorithms for sequence analysis are known in the art and include ADVANCE and ADAM as described in Torellis and Robotti (1994) *Comput. Appl. Biosci.*, 10:3-5; and FASTA described in Pearson and Lipman (1988) *Proc. Natl. Acad. Sci.* 85:2444-8. Within FASTA, ktup is a control option that sets the sensitivity and speed of the search. If ktup=2, similar regions in the two sequences being compared are found by looking at pairs of

aligned residues; if ktup=1, single aligned amino acids are examined. ktup can be set to 2 or 1 for protein sequences, or from 1 to 6 for DNA sequences. The default if ktup is not specified is 2 for proteins and 6 for DNA. For a further description of FASTA parameters, see <http://bioweb.pasteur.fr/docs/man/man/fasta.1.html#sect2>, the contents of which are
5 incorporated herein by reference.

The percent identity between two sequences can be determined using techniques similar to those described above, with or without allowing gaps. In calculating percent identity, typically exact matches are counted.

As used herein, the phrase "allelic variant" refers to a nucleotide sequence which
10 occurs at a given locus or to a polypeptide encoded by the nucleotide sequence. For example, the TANGO 457 gene exhibits significant homology with a portion of human chromosome 11p14.3 PAC present in a clone designated pDJ239b22 and having GENBANK™ accession number AC003969; the TANGO 416 gene exhibits significant homology with a portion of chromosome 4 between chromosomal markers D4S422 and
15 D4S1576; the INTERCEPT 400 gene exhibits significant homology with a portion of chromosome 4 between markers D4S1616 and D4S1611; the TANGO 331 gene exhibits significant homology with a portion of chromosome 22 at 22q11-q13, between markers WI-4572 and WI-8917; the TANGO 265 gene exhibits significant homology with a portion of chromosome 1 between markers D1S305 and D1S2635; and the TANGO 286 gene exhibits
20 significant homology with a portion of chromosome 22 at 22q12-13. Allelic variants of any of these genes can be identified by sequencing the corresponding chromosomal portion at the indicated location in multiple individuals.

As used herein, the terms "gene" and "recombinant gene" refer to nucleic acid molecules comprising an open reading frame encoding a polypeptide of the invention. Such
25 natural allelic variations can typically result in 1-5% variance in the nucleotide sequence of a given gene. Alternative alleles can be identified by sequencing the gene of interest in a number of different individuals. This can be readily carried out by using hybridization probes to identify the same genetic locus in a variety of individuals. Any and all such

nucleotide variations and resulting amino acid polymorphisms or variations that are the result of natural allelic variation and that do not alter the functional activity are intended to be within the scope of the invention.

Moreover, nucleic acid molecules encoding proteins of the invention from other species (homologs), which have a nucleotide sequence which differs from that of the human proteins described herein are within the scope of the invention. Nucleic acid molecules corresponding to natural allelic variants and homologs of a cDNA of the invention can be isolated based on their identity to human nucleic acid molecules using the human cDNAs, or a portion thereof, as a hybridization probe according to standard hybridization techniques under stringent hybridization conditions. For example, a cDNA encoding a soluble form of a membrane-bound protein of the invention can be isolated based on its hybridization with a nucleic acid molecule encoding all or part of the membrane-bound form. Likewise, a cDNA encoding a membrane-bound form can be isolated based on its hybridization with a nucleic acid molecule encoding all or part of the soluble form.

Accordingly, in another embodiment, an isolated nucleic acid molecule of the invention is at least 15 (25, 40, 60, 80, 100, 150, 200, 250, 300, 350, 400, 450, 500, 600, 700, 800, 900, 1000, 1200, 1400, 1600, 1800, 2000, 2200, 2400, 2600, 2800, 3000, 3500, 4000, 4500, 5000, or more) nucleotides in length and hybridizes under stringent conditions to the nucleic acid molecule comprising the nucleotide sequence, preferably the coding sequence, of any of SEQ ID NOs: 1, 2, 31, 32, 51, 52, 71, 72, 81, 82, 91, 92, 96, 97, 101, 102, 106, 107, 111, 112, 121, 122, 141, 142, 151, 152, 161, 162, 171, 172, 181, 182, 191, 192, 201, 202, 215, 217, 221, 222, 241, 242, 251, 252, 271, 272, 279, 280, 303, 304, 308, 309, 324, 325, 329, 330, 351, 352, 362, 371, 372, 379, 380, 387, 388, 403, 404, 415, 416, 423, 424, 437, 438, and the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764, or a complement thereof. As used herein, the term "hybridizes under stringent conditions" is intended to describe conditions for hybridization and washing under which nucleotide

sequences at least 60% (65%, 70%, preferably 75%) identical to each other typically remain hybridized with each other. Such stringent conditions are known to those skilled in the art and can be found in Current Protocols in Molecular Biology, John Wiley & Sons, N.Y. (1989), 6.3.1-6.3.6. An example of stringent hybridization conditions are hybridization in 6× sodium chloride/sodium citrate (SSC) at about 45°C, followed by one or more washes in 0.2× SSC, 0.1% SDS at 50-65°C. Preferably, an isolated nucleic acid molecule of the invention that hybridizes under stringent conditions to the sequence of any of SEQ ID NOs: 1, 2, 31, 32, 51, 52, 71, 72, 81, 82, 91, 92, 96, 97, 101, 102, 106, 107, 111, 112, 121, 122, 141, 142, 151, 152, 161, 162, 171, 172, 181, 182, 191, 192, 201, 202, 215, 217, 221, 222, 241, 242, 251, 252, 271, 272, 279, 280, 303, 304, 308, 309, 324, 325, 329, 330, 351, 352, 362, 371, 372, 379, 380, 387, 388, 403, 404, 415, 416, 423, 424, 437, 438, and the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764, or a complement thereof, corresponds to a naturally-occurring nucleic acid molecule. As used herein, a "naturally-occurring" nucleic acid molecule refers to an RNA or DNA molecule having a nucleotide sequence that occurs in nature (e.g., encodes a natural protein).

In addition to naturally-occurring allelic variants of a nucleic acid molecule of the invention sequence that can exist in the population, the skilled artisan will further appreciate that changes can be introduced by mutation thereby leading to changes in the amino acid sequence of the encoded protein, without altering the biological activity of the protein. For example, one can make nucleotide substitutions leading to amino acid substitutions at "non-essential" amino acid residues. A "non-essential" amino acid residue is a residue that can be altered from the wild-type sequence without altering the biological activity, whereas an "essential" amino acid residue is required for biological activity. For example, amino acid residues that are not conserved or only semi-conserved among homologs of various species may be non-essential for activity and thus would be likely targets for alteration. Alternatively, amino acid residues that are conserved among the homologs of various species

(e.g., murine and human) may be essential for activity and thus would not be likely targets for alteration.

Accordingly, another aspect of the invention pertains to nucleic acid molecules encoding a polypeptide of the invention that contain changes in amino acid residues that are not essential for activity. Such polypeptides differ in amino acid sequence from any of SEQ ID NOs: 3-8, 33, 35, 38, 53-60, 73-78, 83-85, 93-95, 98-100, 103-105, 108-110, 113-115, 123-131, 143-145, 153-160, 163, 173-175, 183-185, 193-198, 203-214, 216, 223-236, 243-252, 253, 273-278, 281-302, 305-307, 310-315, 326-328, 331-333, 353-358, 363-368, 373-378, 381-386, 389-394, 405-414, 417-422, 425-436, and 439, yet retain biological activity.

In one embodiment, the isolated nucleic acid molecule includes a nucleotide sequence encoding a protein that includes an amino acid sequence that is at least about 40% identical, 50%, 60%, 70%, 80%, 90%, 95%, or 98% identical to the amino acid sequence of any of SEQ ID NOs: 3-8, 33, 35, 38, 53-60, 73-78, 83-85, 93-95, 98-100, 103-105, 108-110, 113-115, 123-131, 143-145, 153-160, 163, 173-175, 183-185, 193-198, 203-214, 216, 223-236, 243-252, 253, 273-278, 281-302, 305-307, 310-315, 326-328, 331-333, 353-358, 363-368, 373-378, 381-386, 389-394, 405-414, 417-422, 425-436, and 439, or the amino acid sequence encoded by the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764.

An isolated nucleic acid molecule encoding a variant protein can be created by introducing one or more nucleotide substitutions, additions or deletions into the nucleotide sequence of any of SEQ ID NOs: 1, 2, 31, 32, 51, 52, 71, 72, 81, 82, 91, 92, 96, 97, 101, 102, 106, 107, 111, 112, 121, 122, 141, 142, 151, 152, 161, 162, 171, 172, 181, 182, 191, 192, 201, 202, 215, 217, 221, 222, 241, 242, 251, 252, 271, 272, 279, 280, 303, 304, 308, 309, 324, 325, 329, 330, 351, 352, 362, 371, 372, 379, 380, 387, 388, 403, 404, 415, 416, 423, 424, 437, 438, and the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764,

such that one or more amino acid residue substitutions, additions or deletions are introduced into the encoded protein. Mutations can be introduced by standard techniques, such as site-directed mutagenesis and PCR-mediated mutagenesis. Preferably, conservative amino acid substitutions are made at one or more predicted non-essential amino acid residues. A

5 "conservative amino acid substitution" is one in which the amino acid residue is replaced with an amino acid residue having a similar side chain. Families of amino acid residues having similar side chains have been defined in the art. These families include amino acids with basic side chains (e.g., lysine, arginine, histidine), acidic side chains (e.g., aspartic acid, glutamic acid), uncharged polar side chains (e.g., glycine, asparagine, glutamine, serine, 10 threonine, tyrosine, cysteine), non-polar side chains (e.g., alanine, valine, leucine, isoleucine, proline, phenylalanine, methionine, tryptophan), beta-branched side chains (e.g., threonine, valine, isoleucine) and aromatic side chains (e.g., tyrosine, phenylalanine, tryptophan, histidine). Alternatively, mutations can be introduced randomly along all or part of the coding sequence, such as by saturation mutagenesis, and the resultant mutants can be 15 screened for biological activity to identify mutants that retain activity. Following mutagenesis, the encoded protein can be expressed recombinantly and the activity of the protein can be determined.

In one embodiment, a mutant polypeptide that is a variant of a polypeptide of the invention can be assayed for: (1) the ability to form protein:protein interactions with a 20 polypeptide of the invention; (2) the ability to bind a ligand of a polypeptide of the invention; (3) the ability to bind with a modulator or substrate of a polypeptide of the invention; (4) the ability to modulate a physiological activity of a polypeptide of the invention, such as one of those disclosed herein; or (5) the ability to catalyze a reaction catalyzed by a polypeptide of the invention.

25 The present invention encompasses antisense nucleic acid molecules, i.e., molecules which are complementary to a sense nucleic acid encoding a polypeptide of the invention, e.g., complementary to the coding strand of a double-stranded cDNA molecule or complementary to an mRNA sequence. Accordingly, an antisense nucleic acid can hydrogen

bond to a sense nucleic acid. The antisense nucleic acid can be complementary to an entire coding strand, or to only a portion thereof, e.g., all or part of the protein coding region (or open reading frame). An antisense nucleic acid molecule can be antisense to all or part of a non-coding region of the coding strand of a nucleotide sequence encoding a polypeptide of the invention. The non-coding regions ("5' and 3' non-translated regions") are the 5' and 3' sequences which flank the coding region and are not translated into amino acids.

An antisense oligonucleotide can be, for example, about 5, 10, 15, 20, 25, 30, 35, 40, 45, or 50 or more nucleotides in length. An antisense nucleic acid of the invention can be constructed using chemical synthesis and enzymatic ligation reactions using procedures known in the art. For example, an antisense nucleic acid (e.g., an antisense oligonucleotide) can be chemically synthesized using naturally occurring nucleotides or variously modified nucleotides designed to increase the biological stability of the molecules or to increase the physical stability of the duplex formed between the antisense and sense nucleic acids, e.g., phosphorothioate derivatives and acridine substituted nucleotides can be used. Examples of modified nucleotides which can be used to generate the antisense nucleic acid include 5-fluorouracil, 5-bromouracil, 5-chlorouracil, 5-iodouracil, hypoxanthine, xanthine, 4-acetylcytosine, 5-(carboxyhydroxymethyl) uracil, 5-carboxymethylaminomethyl-2-thiouridine, 5-carboxymethylaminomethyluracil, dihydrouracil, beta-D-galactosylqueosine, inosine, N₆-isopentenyladenine, 1-methylguanine, 1-methylinosine, 2,2-dimethylguanine, 2-methyladenine, 2-methylguanine, 3-methylcytosine, 5-methylcytosine, N₆-adenine, 7-methylguanine, 5-methylaminomethyluracil, 5-methoxyaminomethyl-2-thiouracil, beta-D-mannosylqueosine, 5'-methoxycarboxymethyluracil, 5-methoxyuracil, 2-methylthio-N₆-isopentenyladenine, uracil-5-oxyacetic acid (v), wybutoxosine, pseudouracil, queosine, 2-thiocytosine, 5-methyl-2-thiouracil, 2-thiouracil, 4-thiouracil, 5-methyluracil, uracil-5-oxyacetic acid methylester, uracil-5-oxyacetic acid (v), 5-methyl-2-thiouracil, 3-(3-amino-3-N-2-carboxypropyl) uracil, (acp3)w, and 2,6-diaminopurine. Alternatively, the antisense nucleic acid can be produced biologically using an expression vector into which a nucleic acid has been sub-cloned in an antisense orientation (i.e., RNA transcribed from the inserted

nucleic acid will be of an antisense orientation to a target nucleic acid of interest, described further in the following subsection).

The antisense nucleic acid molecules of the invention are typically administered to a subject or generated in situ such that they hybridize with or bind with cellular mRNA and/or genomic DNA encoding a selected polypeptide of the invention to thereby inhibit expression, e.g., by inhibiting transcription and/or translation. The hybridization can be by conventional nucleotide complementarity to form a stable duplex, or, for example, in the case of an antisense nucleic acid molecule which binds with DNA duplexes, through specific interactions in the major groove of the double helix. An example of a route of administration of antisense nucleic acid molecules of the invention includes direct injection at a tissue site. Alternatively, antisense nucleic acid molecules can be modified to target selected cells and then administered systemically. For example, for systemic administration, antisense molecules can be modified such that they specifically bind with receptors or antigens expressed on a selected cell surface, e.g., by linking the antisense nucleic acid molecules to peptides or antibodies which bind with cell surface receptors or antigens. The antisense nucleic acid molecules can also be delivered to cells using the vectors described herein. To achieve sufficient intracellular concentrations of the antisense molecules, vector constructs in which the antisense nucleic acid molecule is placed under the control of a strong pol II or pol III promoter are preferred.

An antisense nucleic acid molecule of the invention can be an α -anomeric nucleic acid molecule. An α -anomeric nucleic acid molecule forms specific double-stranded hybrids with complementary RNA in which the strands run parallel to each other (Gaultier et al. (1987) Nucleic Acids Res. 15:6625-6641). The antisense nucleic acid molecule can also comprise a 2'-o-methylribonucleotide (Inoue et al. (1987) Nucleic Acids Res. 15:6131-6148) or a chimeric RNA-DNA analogue (Inoue et al. (1987) FEBS Lett. 215:327-330).

The invention also encompasses ribozymes. Ribozymes are catalytic RNA molecules which are capable of cleaving a single-stranded nucleic acid, such as an mRNA, to which they have a complementary region. Thus, ribozymes (e.g., hammerhead ribozymes as

described in Haselhoff and Gerlach (1988) Nature 334:585-591) can be used to catalytically cleave mRNA transcripts to thereby inhibit translation of the protein encoded by the mRNA. A ribozyme having specificity for a nucleic acid molecule encoding a polypeptide of the invention can be designed based upon the nucleotide sequence of a cDNA disclosed herein.

5 For example, a derivative of a Tetrahymena L-19 IVS RNA can be constructed in which the nucleotide sequence of the ribozyme active site is complementary to the nucleotide sequence to be cleaved, as described in Cech et al. U.S. Patent No. 4,987,071; and Cech et al. U.S. Patent No. 5,116,742. Alternatively, an mRNA encoding a polypeptide of the invention can be used to select a catalytic RNA having a specific ribonuclease activity from a pool of RNA
10 molecules. See, e.g., Bartel and Szostak (1993) Science 261:1411-1418.

The invention includes nucleic acid molecules which form triple helical structures. For example, expression of a polypeptide of the invention can be inhibited by targeting nucleotide sequences complementary to the regulatory region of the gene encoding the polypeptide (e.g., the promoter and/or enhancer) to form triple helical structures that prevent
15 transcription of the gene in target cells. See generally Helene (1991) Anticancer Drug Des. 6(6):569-84; Helene (1992) Ann. N.Y. Acad. Sci. 660:27-36; and Maher (1992) Bioassays 14(12):807-15. "Expression" of a polypeptide, as used herein, refers individually and collectively to the processes of transcription of DNA to generate an RNA transcript and translation of an RNA to generate the polypeptide.

20 In various embodiments, the nucleic acid molecules of the invention can be modified at the base moiety, sugar moiety, or phosphate backbone to improve, e.g., the stability, hybridization, or solubility of the molecule. For example, the deoxyribose phosphate backbone of the nucleic acids can be modified to generate peptide nucleic acids (see Hyrup et al. (1996) Bioorganic & Medicinal Chemistry 4(1): 5-23). As used herein, the terms "peptide
25 nucleic acids" or "PNAs" refer to nucleic acid mimics, e.g., DNA mimics, in which the deoxyribose phosphate backbone is replaced by a pseudopeptide backbone and only the four natural nucleobases are retained. The neutral backbone of PNAs has been shown to allow specific hybridization with DNA and RNA under conditions of low ionic strength. Synthesis

of PNA oligomers can be performed using standard solid phase peptide synthesis protocols such as those described in Hyrup et al. (1996), supra; Perry-O'Keefe et al. (1996) Proc. Natl. Acad. Sci. USA 93: 14670-675.

PNAs can be used in therapeutic and diagnostic applications. For example, PNAs can be used as antisense or anti-gene agents for sequence-specific modulation of gene expression by, e.g., inducing arrest of transcription or translation or by inhibiting replication. PNAs can also be used, e.g., in the analysis of single base pair mutations in a gene by, e.g., PNA directed PCR clamping; as artificial restriction enzymes when used in combination with other enzymes, e.g., S1 nucleases (Hyrup (1996), supra; or as probes or primers for DNA sequence and hybridization (Hyrup (1996), supra; Perry-O'Keefe et al. (1996) Proc. Natl. Acad. Sci. USA 93: 14670-675).

In another embodiment, PNAs can be modified, e.g., to enhance their stability or cellular uptake, by attaching lipophilic or other helper groups to PNA, by formation of PNA-DNA chimeras, or by use of liposomes or other techniques of drug delivery known in the art. For example, PNA-DNA chimeras can be generated which can combine the advantageous properties of PNA and DNA. Such chimeras allow DNA recognition enzymes, e.g., RNase H and DNA polymerases, to interact with the DNA portion while the PNA portion provides high binding affinity and specificity. PNA-DNA chimeras can be linked using linkers of appropriate lengths selected in terms of base stacking, number of bonds between the nucleobases, and orientation (Hyrup (1996), supra). The synthesis of PNA-DNA chimeras can be performed as described in Hyrup (1996), supra, and Finn et al. (1996) Nucleic Acids Res. 24(17):3357-63. For example, a DNA chain can be synthesized on a solid support using standard phosphoramidite coupling chemistry and modified nucleoside analogs. Compounds such as 5'-(4-methoxytrityl)amino-5'-deoxy-thymidine phosphoramidite can be used as a link between the PNA and the 5' end of DNA (Mag et al. (1989) Nucleic Acids Res. 17:5973-88). PNA monomers are then coupled in a step-wise manner to produce a chimeric molecule with a 5' PNA segment and a 3' DNA segment (Finn et al. (1996) Nucleic Acids Res. 24(17):3357-63). Alternatively, chimeric molecules can be synthesized with a 5' DNA

segment and a 3' PNA segment (Peterser et al. (1975) Bioorganic Med. Chem. Lett. 5:1119-11124).

In other embodiments, the oligonucleotide can include other appended groups such as peptides (e.g., for targeting host cell receptors in vivo), or agents facilitating transport across the cell membrane (see, e.g., Letsinger et al. (1989) Proc. Natl. Acad. Sci. USA 86:6553-6556; Lemaitre et al. (1987) Proc. Natl. Acad. Sci. USA 84:648-652; PCT Publication No. WO 88/09810) or the blood-brain barrier (see, e.g., PCT Publication No. WO 89/10134). In addition, oligonucleotides can be modified with hybridization-triggered cleavage agents (see, e.g., Krol et al. (1988) Bio/Techniques 6:958-976) or intercalating agents (see, e.g., Zon (1988) Pharm. Res. 5:539-549). To this end, the oligonucleotide can be conjugated with another molecule, e.g., a peptide, hybridization triggered cross-linking agent, transport agent, hybridization-triggered cleavage agent, etc.

II. Isolated Proteins and Antibodies

One aspect of the invention pertains to isolated proteins, and biologically active portions thereof, as well as polypeptide fragments suitable for use as immunogens to generate antibodies directed against a polypeptide of the invention. In one embodiment, the native polypeptide is isolated from cells or tissue sources by an appropriate purification scheme using standard protein purification techniques. In another embodiment, polypeptides of the invention are produced by recombinant DNA techniques. As an alternative to recombinant expression, a polypeptide of the invention can be synthesized chemically using standard peptide synthesis techniques.

An "isolated" or "purified" protein or biologically active portion thereof is substantially free of cellular material or other contaminating proteins from the cell or tissue source from which the protein is derived, or substantially free of chemical precursors or other chemicals, when chemically synthesized. The language "substantially free of cellular material" includes preparations of protein in which the protein is separated from cellular components of the cells from which it is isolated or recombinantly produced. Thus, protein

that is substantially free of cellular material includes preparations of protein having less than about 30%, 20%, 10%, or 5% (by dry weight) of heterologous protein (also referred to herein as a "contaminating protein"). When the protein or biologically active portion thereof is recombinantly produced, it is also preferably substantially free of culture medium, i.e.,
5 culture medium represents less than about 20%, 10%, or 5% of the volume of the protein preparation. When the protein is produced by chemical synthesis, it is preferably substantially free of chemical precursors or other chemicals, i.e., it is separated from chemical precursors or other chemicals which are involved in the synthesis of the protein. Accordingly such preparations of the protein have less than about 30%, 20%, 10%, 5% (by
10 dry weight) of chemical precursors or compounds other than the polypeptide of interest.

Biologically active portions of a polypeptide of the invention include polypeptide regions having an amino acid sequence sufficiently identical to or derived from the amino acid sequence of the protein (e.g., the amino acid sequence shown in any of SEQ ID NOs: 3-8, 33, 35, 38, 53-60, 73-78, 83-85, 93-95, 98-100, 103-105, 108-110, 113-115, 123-131, 143-
15 145, 153-160, 163, 173-175, 183-185, 193-198, 203-214, 216, 223-236, 243-252, 253, 273-278, 281-302, 305-307, 310-315, 326-328, 331-333, 353-358, 363-368, 373-378, 381-386, 389-394, 405-414, 417-422, 425-436, and 439, or the amino acid sequence encoded by the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-
20 424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764), which include fewer amino acids than the full length protein, and exhibit at least one activity of the corresponding full-length protein. Typically, biologically active portions comprise a domain or motif with at least one activity of the corresponding protein. A biologically active portion of a protein of the invention can be a polypeptide which is, for example, 10, 25, 50, 100 or more amino
25 acids in length. Moreover, other biologically active portions, in which other regions of the protein are deleted, can be prepared by recombinant techniques and evaluated for one or more of the functional activities of the native form of a polypeptide of the invention.

Examples of polypeptides have the amino acid sequence of any of SEQ ID NOs: 3-8, 33, 35, 38, 53-60, 73-78, 83-85, 93-95, 98-100, 103-105, 108-110, 113-115, 123-131, 143-145, 153-160, 163, 173-175, 183-185, 193-198, 203-214, 216, 223-236, 243-252, 253, 273-278, 281-302, 305-307, 310-315, 326-328, 331-333, 353-358, 363-368, 373-378, 381-386, 389-394, 405-414, 417-422, 425-436, and 439 or the amino acid sequence encoded by the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764. Other useful proteins are substantially identical (e.g., at least about 40%, preferably 50%, 60%, 70%, 80%, 90%, 95%, or 99%) to any of SEQ ID NOs: 3-8, 33, 35, 38, 53-60, 73-78, 83-85, 93-95, 98-100, 103-105, 108-110, 113-115, 123-131, 143-145, 153-160, 163, 173-175, 183-185, 193-198, 203-214, 216, 223-236, 243-252, 253, 273-278, 281-302, 305-307, 310-315, 326-328, 331-333, 353-358, 363-368, 373-378, 381-386, 389-394, 405-414, 417-422, 425-436, and 439 or the amino acid sequence encoded by the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764 and retain the functional activity of the protein of the corresponding naturally-occurring protein. Such proteins can differ in amino acid sequence owing, for example, to natural allelic variation or mutagenesis.

The invention also provides chimeric or fusion proteins. As used herein, a "chimeric protein" or "fusion protein" comprises all or part (preferably biologically active) of a polypeptide of the invention operably linked with a heterologous polypeptide (i.e., a polypeptide other than the same polypeptide of the invention). Within the fusion protein, the term "operably linked" is intended to indicate that the polypeptide of the invention and the heterologous polypeptide are fused in-frame with each other. The heterologous polypeptide can be fused with the amino-terminus or the carboxyl-terminus of the polypeptide of the invention.

One useful fusion protein is a GST fusion protein in which the polypeptide of the invention is fused with the carboxyl terminus of GST sequences. Such fusion proteins can facilitate purification of a recombinant polypeptide of the invention.

5 In another embodiment, the fusion protein contains a heterologous signal sequence at its amino terminus. For example, the native signal sequence of a polypeptide of the invention can be removed and replaced with a signal sequence from another protein. For example, the gp67 secretory sequence of the baculovirus envelope protein can be used as a heterologous signal sequence (Current Protocols in Molecular Biology, Ausubel et al., eds., John Wiley & Sons, 1992). Other examples of eukaryotic heterologous signal sequences
10 include the secretory sequences of melittin and human placental alkaline phosphatase (Stratagene; La Jolla, California). In yet another example, useful prokaryotic heterologous signal sequences include the phoA secretory signal (Sambrook et al., supra) and the protein A secretory signal (Pharmacia Biotech; Piscataway, New Jersey).

15 In yet another embodiment, the fusion protein is an immunoglobulin fusion protein in which all or part of a polypeptide of the invention is fused with sequences derived from a member of the immunoglobulin protein family. The immunoglobulin fusion proteins of the invention can be incorporated into pharmaceutical compositions and administered to a subject to inhibit an interaction between a ligand (soluble or membrane-bound) and a protein on the surface of a cell (receptor), to thereby suppress signal transduction in vivo. The
20 immunoglobulin fusion protein can be used to affect the bioavailability of a cognate ligand of a polypeptide of the invention. Inhibition of ligand / receptor interaction can be useful therapeutically, both for treating proliferative and differentiative disorders and for modulating (e.g., promoting or inhibiting) cell survival. Moreover, the immunoglobulin fusion proteins of the invention can be used as immunogens to produce antibodies directed
25 against a polypeptide of the invention in a subject, to purify ligands and in screening assays to identify molecules which inhibit the interaction of receptors with ligands. The immunoglobulin fusion protein can, for example, comprise a portion of a polypeptide of the invention fused with the amino-terminus or the carboxyl-terminus of an immunoglobulin

constant region, as disclosed in U.S. Patent No. 5,714,147, U.S. Patent No. 5,116,964, U.S. Patent No. 5,514,582, and U.S. Patent No. 5,455,165.

Chimeric and fusion proteins of the invention can be produced by standard recombinant DNA techniques. In another embodiment, the fusion gene can be synthesized
5 by conventional techniques including automated DNA synthesizers. Alternatively, PCR amplification of gene fragments can be performed using anchor primers which give rise to complementary overhangs between two consecutive gene fragments and which can subsequently be annealed and re-amplified to generate a chimeric gene sequence (see, e.g., Ausubel et al., supra). Moreover, many expression vectors are commercially available that
10 already encode a fusion moiety (e.g., a GST polypeptide). A nucleic acid encoding a polypeptide of the invention can be cloned into such an expression vector such that the fusion moiety is linked in-frame to the polypeptide of the invention.

A signal sequence of a polypeptide of the invention (e.g., the signal sequence in any of SEQ ID NOs: 3, 33, 53, 73, 83, 93, 98, 103, 108, 113, 123, 143, 153, 163, 173, 183, 193,
15 203, 216, 223, 243, 253, 273, 281, 305, 310, 326, 331, 353, 363, 381, 389, 405, 417, 425, and 439) can be used to facilitate secretion and isolation of the secreted protein or another protein of interest. Signal sequences are typically characterized by a core of hydrophobic amino acids which are generally cleaved from the mature protein during secretion in one or more cleavage events. Such signal peptides contain processing sites that allow cleavage of the
20 signal sequence from the mature proteins as they pass through the secretory pathway. Thus, the invention pertains to the described polypeptides having a signal sequence, as well as to the signal sequence itself and to the polypeptide in the absence of the signal sequence (i.e., the cleavage products). In one embodiment, a nucleic acid sequence encoding a signal sequence of the invention can be operably linked in an expression vector with a protein of
25 interest, such as a protein which is ordinarily not secreted or is otherwise difficult to isolate. The signal sequence directs secretion of the protein, such as from a eukaryotic host into which the expression vector is transformed, and the signal sequence is subsequently or concurrently cleaved. The protein can then be readily purified from the extracellular medium

by art recognized methods. Alternatively, the signal sequence can be linked with the protein of interest using a sequence which facilitates purification, such as with a GST domain.

In another embodiment, the signal sequences of the present invention can be used to identify regulatory sequences, e.g., promoters, enhancers, repressors. Since signal sequences are the most amino-terminal sequences of a peptide, the nucleic acids which flank the signal sequence on its amino-terminal side are likely regulatory sequences which affect transcription. Thus, a nucleotide sequence which encodes all or a portion of a signal sequence can be used as a probe to identify and isolate signal sequences and their flanking regions, and these flanking regions can be studied to identify regulatory elements therein.

The present invention also pertains to variants of the polypeptides of the invention. Such variants have an altered amino acid sequence which can function as either agonists (mimetics) or as antagonists. Variants can be generated by mutagenesis, e.g., discrete point mutation or truncation. An agonist can retain substantially the same, or a subset, of the biological activities of the naturally occurring form of the protein. An antagonist of a protein can inhibit one or more of the activities of the naturally occurring form of the protein by, for example, competitively binding with a downstream or upstream member of a cellular signaling cascade which includes the protein of interest. Thus, specific biological effects can be elicited by treatment with a variant of limited function. Treatment of a subject with a variant having a subset of the biological activities of the naturally occurring form of the protein can have fewer side effects in a subject, relative to treatment with the naturally occurring form of the protein.

Variants of a protein of the invention which function as either agonists (e.g., mimetics) or as antagonists can be identified by screening combinatorial libraries of mutants, e.g., truncation mutants, of the protein of the invention for agonist or antagonist activity. In one embodiment, a variegated library of variants is generated by combinatorial mutagenesis at the nucleic acid level and is encoded by a variegated gene library. A variegated library of variants can be produced by, for example, enzymatically ligating a mixture of synthetic oligonucleotides into gene sequences such that a degenerate set of potential protein

sequences can be expressed as individual polypeptides, or alternatively, as a set of larger fusion proteins (e.g., for phage display). There are a variety of methods which can be used to produce libraries of potential variants of the polypeptides of the invention from a degenerate oligonucleotide sequence. Methods for synthesizing degenerate oligonucleotides are known in the art (see, e.g., Narang (1983) Tetrahedron 39:3; Itakura et al. (1984) Annu. Rev. Biochem. 53:323; Itakura et al. (1984) Science 198:1056; Ike et al. (1983) Nucleic Acid Res. 11:477).

In addition, libraries of fragments of the coding sequence of a polypeptide of the invention can be used to generate a variegated population of polypeptides for screening and subsequent selection of variants. For example, a library of coding sequence fragments can be generated by treating a double stranded PCR fragment of the coding sequence of interest with a nuclease under conditions wherein nicking occurs only about once per molecule, denaturing the double stranded DNA, re-naturing the DNA to form double stranded DNA which can include sense / antisense pairs from different nicked products, removing single stranded portions from reformed duplexes by treatment with S1 nuclease, and ligating the resulting fragment library into an expression vector. By this method, an expression library can be derived which encodes amino terminal and internal fragments of various sizes of the protein of interest.

Several techniques are known in the art for screening gene products of combinatorial libraries made by point mutations or truncation, and for screening cDNA libraries for gene products having a selected property. The most widely used techniques, which are amenable to high through-put analysis, for screening large gene libraries typically include cloning the gene library into replicable expression vectors, transforming appropriate cells with the resulting library of vectors, and expressing the combinatorial genes under conditions in which detection of a desired activity facilitates isolation of the vector encoding the gene whose product was detected. Recursive ensemble mutagenesis (REM), a technique which enhances the frequency of functional mutants in the libraries, can be used in combination with the screening assays to identify variants of a protein of the invention (Arkin and

Yourvan (1992) Proc. Natl. Acad. Sci. USA 89:7811-7815; Delgrave et al. (1993) Protein Engineering 6(3):327-331).

An isolated polypeptide of the invention, or a fragment thereof, can be used as an immunogen to generate antibodies using standard techniques for polyclonal and monoclonal antibody preparation. The full-length polypeptide or protein can be used or, alternatively, the invention provides antigenic peptide fragments for use as immunogens. The antigenic peptide of a protein of the invention comprises at least 10 (preferably 12, 15, 20, or 30 or more) amino acid residues of the amino acid sequence of any of SEQ ID NOs: 3-8, 33, 35, 38, 53-60, 73-78, 83-85, 93-95, 98-100, 103-105, 108-110, 113-115, 123-131, 143-145, 153-160, 163, 173-175, 183-185, 193-198, 203-214, 216, 223-236, 243-252, 253, 273-278, 281-302, 305-307, 310-315, 326-328, 331-333, 353-358, 363-368, 373-378, 381-386, 389-394, 405-414, 417-422, 425-436, and 439 or the amino acid sequence encoded by the nucleotide sequence of any of the clones deposited as ATCC® Accession numbers 207184, 207219, 207220, 207221, 207228, 207230, PTA-147, PTA-150, PTA-151, PTA-295, PTA-424, PTA-438, PTA-455, PTA-817, PTA-1156, and PTA-1764, and encompasses an epitope of the protein such that an antibody raised against the peptide forms a specific immune complex with the protein.

Examples of epitopes encompassed by the antigenic peptide are regions that are located on the surface of the protein, e.g., hydrophilic regions. Figures 3, 8, 10G, 11Y-1 through 11Y-6, 11Z-6, 12D, 13B, 14B, 15E, 15J, 16E, 17G, 18D, 18G, 19F, 19L, 20D, 21E, 22D, 22M, 23D, 24F, 25L, 25M, 26J, 27U, 28E, 29F, and 30D are hydrophobicity plots of proteins of the invention. These or similar analyses can be used to identify hydrophilic regions.

An immunogen typically is used to prepare antibodies by immunizing a suitable (i.e., immunocompetent) subject such as a rabbit, goat, mouse, or other mammal or vertebrate. An appropriate immunogenic preparation can contain, for example, recombinantly-expressed or chemically-synthesized polypeptide. The preparation can further include an adjuvant, such as Freund's complete or incomplete adjuvant, or a similar immunostimulatory agent.

Accordingly, another aspect of the invention pertains to antibodies directed against a polypeptide of the invention. The terms "antibody" and "antibody substance" as used interchangeably herein refer to immunoglobulin molecules and immunologically active portions of immunoglobulin molecules, i.e., molecules that contain an antigen binding site which specifically binds an antigen, such as a polypeptide of the invention. A molecule which specifically binds with a given polypeptide of the invention is a molecule which binds the polypeptide, but does not substantially bind other molecules in a sample, e.g., a biological sample, which naturally contains the polypeptide. Examples of immunologically active portions of immunoglobulin molecules include F(ab) and F(ab')₂ fragments which can be generated by treating the antibody with an enzyme such as pepsin. The invention provides polyclonal and monoclonal antibodies. The term "monoclonal antibody" or "monoclonal antibody composition", as used herein, refers to a population of antibody molecules that contain only one species of an antigen binding site capable of immunoreacting with a particular epitope.

Polyclonal antibodies can be prepared as described above by immunizing a suitable subject with a polypeptide of the invention as an immunogen. The antibody titer in the immunized subject can be monitored over time by standard techniques, such as with an enzyme linked immunosorbent assay (ELISA) using immobilized polypeptide. If desired, the antibody molecules can be harvested or isolated from the subject (e.g., from the blood or serum of the subject) and further purified by well-known techniques, such as protein A chromatography to obtain the IgG fraction. At an appropriate time after immunization, e.g., when the specific antibody titers are highest, antibody-producing cells can be obtained from the subject and used to prepare monoclonal antibodies by standard techniques, such as the hybridoma technique originally described by Kohler and Milstein (1975) *Nature* 256:495-497, the human B cell hybridoma technique (Kozbor et al. (1983) *Immunol. Today* 4:72), the EBV-hybridoma technique (Cole et al. (1985), *Monoclonal Antibodies and Cancer Therapy*, Alan R. Liss, Inc., pp. 77-96) or trioma techniques. The technology for producing hybridomas is well known (see generally *Current Protocols in Immunology* (1994) Coligan et

al. (Eds.) John Wiley & Sons, Inc., New York, NY). Hybridoma cells producing a monoclonal antibody of the invention are detected by screening the hybridoma culture supernatants for antibodies that bind the polypeptide of interest, e.g., using a standard ELISA assay.

5 Alternative to preparing monoclonal antibody-secreting hybridomas, a monoclonal antibody directed against a polypeptide of the invention can be identified and isolated by screening a recombinant combinatorial immunoglobulin library (e.g., an antibody phage display library) with the polypeptide of interest. Kits for generating and screening phage display libraries are commercially available (e.g., the Pharmacia Recombinant Phage
10 Antibody System, Catalog No. 27-9400-01; and the Stratagene SurfZAP Phage Display Kit, Catalog No. 240612). Additionally, examples of methods and reagents particularly amenable for use in generating and screening antibody display library can be found in, for example, U.S. Patent No. 5,223,409; PCT Publication No. WO 92/18619; PCT Publication No. WO 91/17271; PCT Publication No. WO 92/20791; PCT Publication No. WO 92/15679; PCT
15 Publication No. WO 93/01288; PCT Publication No. WO 92/01047; PCT Publication No. WO 92/09690; PCT Publication No. WO 90/02809; Fuchs et al. (1991) Bio/Technology 9:1370-1372; Hay et al. (1992) Hum. Antibod. Hybridomas 3:81-85; Huse et al. (1989) Science 246:1275-1281; Griffiths et al. (1993) EMBO J. 12:725-734.

 Recombinant antibodies, such as chimeric and humanized monoclonal antibodies,
20 comprising both human and non-human portions, which can be made using standard recombinant DNA techniques, are within the scope of the invention. Such chimeric and humanized monoclonal antibodies can be produced by recombinant DNA techniques known in the art, for example using methods described in PCT Publication No. WO 87/02671; European Patent Application 184,187; European Patent Application 171,496; European
25 Patent Application 173,494; PCT Publication No. WO 86/01533; U.S. Patent No. 4,816,567; European Patent Application 125,023; Better et al. (1988) Science 240:1041-1043; Liu et al. (1987) Proc. Natl. Acad. Sci. USA 84:3439-3443; Liu et al. (1987) J. Immunol. 139:3521-3526; Sun et al. (1987) Proc. Natl. Acad. Sci. USA 84:214-218; Nishimura et al. (1987)

Cancer Res. 47:999-1005; Wood et al. (1985) Nature 314:446-449; and Shaw et al. (1988) J. Natl. Cancer Inst. 80:1553-1559); Morrison (1985) Science 229:1202-1207; Oi et al. (1986) Bio/Techniques 4:214; U.S. Patent 5,225,539; Jones et al. (1986) Nature 321:552-525; Verhoeyan et al. (1988) Science 239:1534; and Beidler et al. (1988) J. Immunol. 141:4053-4060.

Completely human antibodies are particularly desirable for therapeutic treatment of human patients. Such antibodies can be produced using transgenic mice which are incapable of expressing endogenous immunoglobulin heavy and light chains genes, but which can express human heavy and light chain genes. The transgenic mice are immunized in the normal fashion with a selected antigen, e.g., all or a portion of a polypeptide of the invention. Monoclonal antibodies directed against the antigen can be obtained using conventional hybridoma technology. The human immunoglobulin transgenes harbored by the transgenic mice rearrange during B cell differentiation, and subsequently undergo class switching and somatic mutation. Thus, using such a technique, it is possible to produce therapeutically useful IgG, IgA, and IgE antibodies. For an overview of this technology for producing human antibodies, see Lonberg and Huszar (1995, Int. Rev. Immunol. 13:65-93). For a detailed discussion of this technology for producing human antibodies and human monoclonal antibodies and protocols for producing such antibodies, see, e.g., U.S. Patent 5,625,126; U.S. Patent 5,633,425; U.S. Patent 5,569,825; U.S. Patent 5,661,016; and U.S. Patent 5,545,806. In addition, companies such as Abgenix, Inc. (Freemont, CA), can be engaged to provide human antibodies directed against a selected antigen using technology similar to that described above.

Completely human antibodies which recognize a selected epitope can be generated using a technique referred to as "guided selection." In this approach a selected non-human monoclonal antibody, e.g., a murine antibody, is used to guide the selection of a completely human antibody recognizing the same epitope (Jespers et al. (1994) Bio/technology 12:899-903).

An antibody directed against a polypeptide of the invention (e.g., monoclonal antibody) can be used to isolate the polypeptide by standard techniques, such as affinity chromatography or immunoprecipitation. Moreover, such an antibody can be used to detect the protein (e.g., in a cellular lysate or cell supernatant) in order to evaluate the abundance and pattern of expression of the polypeptide. The antibodies can also be used diagnostically to monitor protein levels in tissue as part of a clinical testing procedure, e.g., to, for example, determine the efficacy of a given treatment regimen. Detection can be facilitated by coupling the antibody to a detectable substance. Examples of detectable substances include various enzymes, prosthetic groups, fluorescent materials, luminescent materials, bioluminescent materials, and radioactive materials. Examples of suitable enzymes include horseradish peroxidase, alkaline phosphatase, β -galactosidase, or acetylcholinesterase; examples of suitable prosthetic group complexes include streptavidin / biotin and avidin / biotin; examples of suitable fluorescent materials include umbelliferone, fluorescein, fluorescein isothiocyanate, rhodamine, dichlorotriazinylamine fluorescein, dansyl chloride or phycoerythrin; an example of a luminescent material includes luminol; examples of bioluminescent materials include luciferase, luciferin, and aequorin, and examples of suitable radioactive material include ^{125}I , ^{131}I , ^{35}S or ^3H .

An antibody (or fragment thereof) can be conjugated to a therapeutic moiety such as a cytotoxin, a therapeutic agent, or a radioactive agent (e.g., a radioactive metal ion).

Cytotoxins and cytotoxic agents include any agent that is detrimental to cells. Examples of such agents include taxol, cytochalasin B, gramicidin D, ethidium bromide, emetine, mitomycin, etoposide, tenoposide, vincristine, vinblastine, colchicin, doxorubicin, daunorubicin, dihydroxy anthracin dione, mitoxantrone, mithramycin, actinomycin D, 1-dehydrotestosterone, glucocorticoids, procaine, tetracaine, lidocaine, propranolol, and puromycin and analogs or homologs thereof. Therapeutic agents include, but are not limited to, antimetabolites (e.g., methotrexate, 6-mercaptopurine, 6-thioguanine, cytarabine, and 5-fluorouracil decarbazine), alkylating agents (e.g., mechlorethamine, thioepa chlorambucil, melphalan, carmustine (BSNU) and lomustine (CCNU), cyclophosphamide, busulfan,

dibromomannitol, streptozotocin, mitomycin C, and cis-dichlorodiamine platinum (II) (DDP) cisplatin), anthracyclines (e.g., daunorubicin {formerly designated daunomycin} and doxorubicin), antibiotics (e.g., dactinomycin {formerly designated actinomycin}, bleomycin, mithramycin, and anthramycin), and anti-mitotic agents (e.g., vincristine and vinblastine).

5 Conjugated antibodies of the invention can be used for modifying a given biological response, the drug moiety not being limited to classical chemical therapeutic agents. For example, the drug moiety can be a protein or polypeptide possessing a desired biological activity. Such proteins include, for example, toxins such as abrin, ricin A, *Pseudomonas* exotoxin, or diphtheria toxin; proteins such as tumor necrosis factor, alpha-interferon, beta-
10 interferon, nerve growth factor, platelet derived growth factor, tissue plasminogen activator; and biological response modifiers such as lymphokines, interleukin-1, interleukin-2, interleukin-6, granulocyte macrophage colony stimulating factor, granulocyte colony stimulating factor, or other growth factors.

Techniques for conjugating a therapeutic moiety to an antibody are well known (see,
15 e.g., Arnon et al., 1985, "Monoclonal Antibodies For Immunotargeting Of Drugs In Cancer Therapy", in *Monoclonal Antibodies And Cancer Therapy*, Reisfeld et al., Eds., Alan R. Liss, Inc. pp. 243-256; Hellstrom et al., 1987, "Antibodies For Drug Delivery", in *Controlled Drug Delivery*, 2nd ed., Robinson et al., Eds., Marcel Dekker, Inc., pp. 623-653; Thorpe, 1985, "Antibody Carriers Of Cytotoxic Agents In Cancer Therapy: A Review", in *Monoclonal*
20 *Antibodies '84: Biological And Clinical Applications*, Pinchera et al., Eds., pp. 475-506; "Analysis, Results, And Future Prospective Of The Therapeutic Use Of Radiolabeled Antibody In Cancer Therapy", in *Monoclonal Antibodies For Cancer Detection And Therapy*, Baldwin et al., Eds., Academic Press, pp. 303-316, 1985; and Thorpe et al., 1982, *Immunol. Rev.*, 62:119-158). Alternatively, an antibody can be conjugated to a second
25 antibody to form an antibody heteroconjugate as described by Segal in U.S. Patent No. 4,676,980.

III. Recombinant Expression Vectors and Host Cells

Another aspect of the invention pertains to vectors, including expression vectors, containing a nucleic acid encoding a polypeptide of the invention (or a portion thereof). As used herein, the term "vector" refers to a nucleic acid molecule capable of transporting another nucleic acid to which it has been linked. One type of vector is a "plasmid", which refers to a circular double stranded DNA loop into which additional DNA segments can be ligated. Another type of vector is a viral vector, wherein additional DNA segments can be ligated into the viral genome. Certain vectors are capable of autonomous replication in a host cell into which they are introduced (e.g., bacterial vectors having a bacterial origin of replication and episomal mammalian vectors). Other vectors (e.g., non-episomal mammalian vectors) are integrated into the genome of a host cell upon introduction into the host cell, and thereby are replicated along with the host genome. Moreover, certain vectors, designated expression vectors, are capable of directing expression of genes with which they are operably linked. In general, expression vectors of utility in recombinant DNA techniques are often in the form of plasmids (vectors). However, the invention is intended to include such other forms of expression vectors, such as viral vectors (e.g., replication defective retroviruses, adenoviruses and adeno-associated viruses), which serve equivalent functions.

The recombinant expression vectors of the invention comprise a nucleic acid of the invention in a form suitable for expression of the nucleic acid in a host cell. This means that the recombinant expression vectors include one or more regulatory sequences, selected on the basis of the host cells to be used for expression, which is operably linked with the nucleic acid sequence to be expressed. Within a recombinant expression vector, "operably linked" is intended to mean that the nucleotide sequence of interest is linked with the regulatory sequence(s) in a manner which allows expression of the nucleotide sequence (e.g., in an in vitro transcription / translation system or in a host cell when the vector is introduced into the host cell). The term "regulatory sequence" is intended to include promoters, enhancers and other expression control elements (e.g., polyadenylation signals). Such regulatory sequences are described, for example, in Goeddel, Gene Expression Technology: Methods in

Enzymology 185, Academic Press, San Diego, CA (1990). Regulatory sequences include those which direct constitutive expression of a nucleotide sequence in many types of host cell and those which direct expression of the nucleotide sequence only in certain host cells (e.g., tissue-specific regulatory sequences). It will be appreciated by those skilled in the art that the design of the expression vector can depend on such factors as the choice of the host cell to be transformed, and the level of expression of protein desired. The expression vectors of the invention can be introduced into host cells to thereby produce proteins or peptides, including fusion proteins or peptides, encoded by nucleic acids as described herein.

The recombinant expression vectors of the invention can be designed for expression of a polypeptide of the invention in prokaryotic (e.g., *E. coli*) or eukaryotic cells (e.g., insect cells (using baculovirus expression vectors), yeast cells or mammalian cells). Suitable host cells are discussed further in Goeddel, *supra*. Alternatively, the recombinant expression vector can be transcribed and translated in vitro, for example using T7 promoter regulatory sequences and T7 polymerase.

Expression of proteins in prokaryotes is most often carried out in *E. coli* with vectors containing constitutive or inducible promoters directing the expression of either fusion or non-fusion proteins. Fusion vectors add a number of amino acids to a protein encoded therein, usually to the amino terminus of the recombinant protein. Such fusion vectors typically serve three purposes: 1) to increase expression of recombinant protein; 2) to increase the solubility of the recombinant protein; and 3) to aid in the purification of the recombinant protein by acting as a ligand in affinity purification. Often, in fusion expression vectors, a proteolytic cleavage site is introduced at the junction of the fusion moiety and the recombinant protein to enable separation of the recombinant protein from the fusion moiety subsequent to purification of the fusion protein. Such enzymes, and their cognate recognition sequences, include Factor Xa, thrombin and enterokinase. Typical fusion expression vectors include pGEX (Pharmacia Biotech Inc; Smith and Johnson (1988) Gene 67:31-40), pMAL (New England Biolabs, Beverly, MA) and pRIT5 (Pharmacia, Piscataway, NJ) which fuse

glutathione S-transferase (GST), maltose E binding protein, or protein A, respectively, to the target recombinant protein.

5 Examples of suitable inducible non-fusion *E. coli* expression vectors include pTrc (Amann et al., (1988) *Gene* 69:301-315) and pET 11d (Studier et al., *Gene Expression Technology: Methods in Enzymology* 185, Academic Press, San Diego, California (1990) 60-89). Target gene expression from the pTrc vector relies on host RNA polymerase transcription from a hybrid *trp-lac* fusion promoter. Target gene expression from the pET 11d vector relies on transcription from a T7 *gn10-lac* fusion promoter mediated by a co-expressed viral RNA polymerase (T7 *gn1*). This viral polymerase is supplied by host strains 10 BL21(DE3) or HMS174(DE3) from a resident λ prophage harboring a T7 *gn1* gene under the transcriptional control of the *lacUV 5* promoter.

One strategy to maximize recombinant protein expression in *E. coli* is to express the protein in a host bacteria having an impaired capacity to proteolytically cleave the recombinant protein (Gottesman, *Gene Expression Technology: Methods in Enzymology* 15 185, Academic Press, San Diego, California (1990) 119-128). Another strategy is to alter the nucleic acid sequence of the nucleic acid to be inserted into an expression vector such that the individual codons for each amino acid are those preferentially used in *E. coli* (Wada et al. (1992) *Nucleic Acids Res.* 20:2111-2118). Such alteration of nucleic acid sequences of the invention can be performed by standard DNA synthesis techniques.

20 In another embodiment, the expression vector is a yeast expression vector. Examples of vectors for expression in yeast *S. cerevisiae* include pYepSec1 (Baldari et al. (1987) *EMBO J.* 6:229-234), pMFa (Kurjan and Herskowitz, (1982) *Cell* 30:933-943), pJRY88 (Schultz et al. (1987) *Gene* 54:113-123), pYES2 (Invitrogen Corporation, San Diego, CA), and pPicZ (Invitrogen Corp, San Diego, CA).

25 Alternatively, the expression vector is a baculovirus expression vector. Baculovirus vectors available for expression of proteins in cultured insect cells (e.g., Sf 9 cells) include the pAc series (Smith et al. (1983) *Mol. Cell Biol.* 3:2156-2165) and the pVL series (Lucklow and Summers (1989) *Virology* 170:31-39).

In yet another embodiment, a nucleic acid of the invention is expressed in mammalian cells using a mammalian expression vector. Examples of mammalian expression vectors include pCDM8 (Seed (1987) Nature 329:840) and pMT2PC (Kaufman et al. (1987) EMBO J. 6:187-195). When used in mammalian cells, the expression vector's control functions are often provided by viral regulatory elements. For example, commonly used promoters are derived from polyoma, Adenovirus 2, cytomegalovirus and Simian Virus 40. For other suitable expression systems for both prokaryotic and eukaryotic cells see chapters 16 and 17 of Sambrook et al., supra.

In another embodiment, the recombinant mammalian expression vector is capable of directing expression of the nucleic acid preferentially in a particular cell type (e.g., tissue-specific regulatory elements are used to express the nucleic acid). Tissue-specific regulatory elements are known in the art. Non-limiting examples of suitable tissue-specific promoters include the albumin promoter (liver-specific; Pinkert et al. (1987) Genes Dev. 1:268-277), lymphoid-specific promoters (Calame and Eaton (1988) Adv. Immunol. 43:235-275), in particular promoters of T cell receptors (Winoto and Baltimore (1989) EMBO J. 8:729-733) and immunoglobulins (Banerji et al. (1983) Cell 33:729-740; Queen and Baltimore (1983) Cell 33:741-748), neuron-specific promoters (e.g., the neurofilament promoter; Byrne and Ruddle (1989) Proc. Natl. Acad. Sci. USA 86:5473-5477), pancreas-specific promoters (Edlund et al. (1985) Science 230:912-916), and mammary gland-specific promoters (e.g., milk whey promoter; U.S. Patent No. 4,873,316 and European Application Publication No. 264,166). Developmentally-regulated promoters are also encompassed, for example the murine hox promoters (Kessel and Gruss (1990) Science 249:374-379) and the α -fetoprotein promoter (Campes and Tilghman (1989) Genes Dev. 3:537-546).

The invention further provides a recombinant expression vector comprising a DNA molecule of the invention cloned into the expression vector in an antisense orientation. That is, the DNA molecule is operably linked with a regulatory sequence in a manner which allows for expression (by transcription of the DNA molecule) of an RNA molecule which is antisense, relative to the mRNA encoding a polypeptide of the invention. Regulatory

sequences operably linked with a nucleic acid cloned in the antisense orientation can be selected which direct continuous expression of the antisense RNA molecule in a variety of cell types, for instance viral promoters and/or enhancers, or regulatory sequences can be selected which direct constitutive, tissue specific, or cell type specific expression of antisense RNA. The antisense expression vector can be in the form of a recombinant plasmid, phagemid, or attenuated virus in which antisense nucleic acids are produced under the control of a high efficiency regulatory region, the activity of which can be determined by the cell type into which the vector is introduced. For a discussion of the regulation of gene expression using antisense genes see Weintraub et al. (Reviews - Trends in Genetics, Vol. 1(1) 1986).

Another aspect of the invention pertains to host cells into which a recombinant expression vector of the invention has been introduced. The terms "host cell" and "recombinant host cell" are used interchangeably herein. It is understood that such terms refer not only to the particular subject cell but to the progeny or potential progeny of such a cell. Because certain modifications can occur in succeeding generations due to either mutation or environmental influences, such progeny may not, in fact, be identical to the parent cell, but are still included within the scope of the term as used herein.

A host cell can be any prokaryotic (e.g., *E. coli*) or eukaryotic cell (e.g., insect cells, yeast or mammalian cells).

Vector DNA can be introduced into prokaryotic or eukaryotic cells via conventional transformation or transfection techniques. As used herein, the terms "transformation" and "transfection" are intended to refer to a variety of art-recognized techniques for introducing foreign nucleic acid into a host cell, including calcium phosphate or calcium chloride coprecipitation, DEAE-dextran-mediated transfection, lipofection, and electroporation.

Suitable methods for transforming or transfecting host cells can be found in Sambrook, et al. (supra), and other laboratory manuals.

For stable transfection of mammalian cells, it is known that, depending upon the expression vector and transfection technique used, only a small fraction of cells integrate the

foreign DNA into their genome. In order to identify and select these integrants, a gene that encodes a selectable marker (e.g., for resistance to antibiotics) can be introduced into the host cells along with the gene of interest. Examples of selectable markers include those which confer resistance to drugs, such as G418, hygromycin and methotrexate. Cells stably
5 transfected with the introduced nucleic acid can be identified by drug selection (e.g., cells that have incorporated the selectable marker gene survive, while other cells die).

A host cell of the invention, such as a prokaryotic or eukaryotic host cell in culture, can be used to produce a polypeptide of the invention. Accordingly, the invention further provides methods for producing a polypeptide of the invention using the host cells of the
10 invention. In one embodiment, the method comprises culturing the host cell of invention (into which a recombinant expression vector encoding a polypeptide of the invention has been introduced) in a suitable medium such that the polypeptide is produced. In another embodiment, the method further comprises isolating the polypeptide from the medium or the host cell.

The host cells of the invention can be used to produce non-human transgenic animals.
15 For example, in one embodiment, a host cell of the invention is a fertilized oocyte or an embryonic stem cell into which a sequences encoding a polypeptide of the invention have been introduced. Such host cells can then be used to create non-human transgenic animals in which exogenous sequences encoding a polypeptide of the invention have been introduced
20 into their genome or homologous recombinant animals in which endogenous encoding a polypeptide of the invention sequences have been altered. Such animals are useful for studying the function and/or activity of the polypeptide and for identifying and/or evaluating modulators of polypeptide activity. As used herein, a "transgenic animal" is a non-human animal, preferably a mammal, more preferably a rodent such as a rat or mouse, in which one
25 or more of the cells of the animal includes a transgene. Other examples of transgenic animals include non-human primates, sheep, dogs, cows, goats, chickens, amphibians, etc. A transgene is exogenous DNA which is integrated into the genome of a cell from which a transgenic animal develops and which remains in the genome of the mature animal, thereby

directing expression of an encoded gene product in one or more cell types or tissues of the transgenic animal. As used herein, an "homologous recombinant animal" is a non-human animal, preferably a mammal, more preferably a mouse, in which an endogenous gene has been altered by homologous recombination between the endogenous gene and an exogenous DNA molecule introduced into a cell of the animal, e.g., an embryonic cell of the animal, prior to development of the animal.

A transgenic animal of the invention can be created by introducing a nucleic acid encoding a polypeptide of the invention (or a homologue thereof) into the male pronuclei of a fertilized oocyte (e.g., by microinjection or retroviral infection) and allowing the oocyte to develop in a pseudopregnant female foster animal. Intronic sequences and polyadenylation signals can also be included in the transgene to increase the efficiency of expression of the transgene. A tissue-specific regulatory sequence(s) can be operably linked with the transgene to direct expression of a polypeptide of the invention to particular cells. Methods for generating transgenic animals via embryo manipulation and microinjection, particularly animals such as mice, have become conventional in the art and are described, for example, in U.S. Patent Nos. 4,736,866 and 4,870,009, U.S. Patent No. 4,873,191 and in Hogan, Manipulating the Mouse Embryo, (Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y., 1986). Similar methods are used for production of other transgenic animals. A transgenic founder animal can be identified based upon the presence of the transgene in its genome and/or expression of mRNA encoding the transgene in tissues or cells of the animals. A transgenic founder animal can be used to breed additional animals carrying the transgene. Moreover, transgenic animals harboring the transgene can further be bred to other transgenic animals harboring other transgenes.

To create an homologous recombinant animal, a vector is prepared which contains at least a portion of a gene encoding a polypeptide of the invention into which a deletion, addition or substitution has been introduced to thereby alter, e.g., functionally disrupt, the gene. In one embodiment, the vector is designed such that, upon homologous recombination, the endogenous gene is functionally disrupted (i.e., no longer encodes a functional protein;

also referred to as a "knock out" vector). Alternatively, the vector can be designed such that, upon homologous recombination, the endogenous gene is mutated or otherwise altered, but still encodes functional protein (e.g., the upstream regulatory region can be altered to thereby alter the expression of the endogenous protein). In the homologous recombination vector, the altered portion of the gene is flanked at its 5' and 3' ends by additional nucleic acid of the gene to allow for homologous recombination to occur between the exogenous gene carried by the vector and an endogenous gene in an embryonic stem cell. The additional flanking nucleic acid sequences are of sufficient length for successful homologous recombination with the endogenous gene. Typically, several kilobases of flanking DNA (both at the 5' and 3' ends) are included in the vector (see, e.g., Thomas and Capecchi (1987) Cell 51:503 for a description of homologous recombination vectors). The vector is introduced into an embryonic stem cell line (e.g., by electroporation) and cells in which the introduced gene has homologously recombined with the endogenous gene are selected (see, e.g., Li et al. (1992) Cell 69:915). The selected cells are then injected into a blastocyst of an animal (e.g., a mouse) to form aggregation chimeras (see, e.g., Bradley in Teratocarcinomas and Embryonic Stem Cells: A Practical Approach, Robertson, ed. (IRL, Oxford, 1987) pp. 113-152). A chimeric embryo can then be implanted into a suitable pseudopregnant female foster animal and the embryo brought to term. Progeny harboring the homologously recombined DNA in their germ cells can be used to breed animals in which all cells of the animal contain the homologously recombined DNA by germline transmission of the transgene. Methods for constructing homologous recombination vectors and homologous recombinant animals are described further in Bradley (1991) Current Opinion in Bio/Technology 2:823-829 and in PCT Publication Numbers WO 90/11354, WO 91/01140, WO 92/0968, and WO 93/04169.

In another embodiment, transgenic non-human animals can be produced which contain selected systems which allow for regulated expression of the transgene. One example of such a system is the cre/loxP recombinase system of bacteriophage P1. For a description of the cre/loxP recombinase system, see, e.g., Lakso et al. (1992) Proc. Natl. Acad. Sci. USA 89:6232-6236. Another example of a recombinase system is the FLP

recombinase system of *Saccharomyces cerevisiae* (O'Gorman et al. (1991) Science 251:1351-1355. If a cre/loxP recombinase system is used to regulate expression of the transgene, animals containing transgenes encoding both the Cre recombinase and a selected protein are required. Such animals can be provided through the construction of "double" transgenic animals, e.g., by mating two transgenic animals, one containing a transgene encoding a selected protein and the other containing a transgene encoding a recombinase.

Clones of the non-human transgenic animals described herein can be produced according to the methods described in Wilmot et al. (1997) Nature 385:810-813 and PCT Publication Numbers WO 97/07668 and WO 97/07669.

IV. Pharmaceutical Compositions

The nucleic acid molecules, polypeptides, and antibodies (also referred to herein as "active compounds") of the invention can be incorporated into pharmaceutical compositions suitable for administration. Such compositions typically comprise the nucleic acid molecule, protein, or antibody and a pharmaceutically acceptable carrier. As used herein the language "pharmaceutically acceptable carrier" is intended to include any and all solvents, dispersion media, coatings, anti-bacterial and anti-fungal agents, isotonic and absorption delaying agents, and the like, compatible with pharmaceutical administration. The use of such media and agents for pharmaceutically active substances is well known in the art. Except insofar as any conventional media or agent is incompatible with the active compound, use thereof in the compositions is contemplated. Supplementary active compounds can also be incorporated into the compositions.

The invention includes methods for preparing pharmaceutical compositions for modulating the expression or activity of a polypeptide or nucleic acid of the invention. Such methods comprise formulating a pharmaceutically acceptable carrier with an agent which modulates expression or activity of a polypeptide or nucleic acid of the invention. Such compositions can further include additional active agents. Thus, the invention further includes methods for preparing a pharmaceutical composition by formulating a

pharmaceutically acceptable carrier with an agent which modulates expression or activity of a polypeptide or nucleic acid of the invention and one or more additional active compounds.

The agent which modulates expression or activity can, for example, be a small molecule. For example, such small molecules include peptides, peptidomimetics, amino acids, amino acid analogs, polynucleotides, polynucleotide analogs, nucleotides, nucleotide analogs, organic or inorganic compounds (i.e., including heteroorganic and organometallic compounds) having a molecular weight less than about 10,000 grams per mole, organic or inorganic compounds having a molecular weight less than about 5,000 grams per mole, organic or inorganic compounds having a molecular weight less than about 1,000 grams per mole, organic or inorganic compounds having a molecular weight less than about 500 grams per mole, and salts, esters, and other pharmaceutically acceptable forms of such compounds.

It is understood that appropriate doses of small molecule agents and protein or polypeptide agents depends upon a number of factors within the ken of the ordinarily skilled physician, veterinarian, or researcher. The dose(s) of these agents will vary, for example, depending upon the identity, size, and condition of the subject or sample being treated, further depending upon the route by which the composition is to be administered, if applicable, and the effect which the practitioner desires the agent to have upon the nucleic acid or polypeptide of the invention. Examples of doses of a small molecule include milligram or microgram amounts per kilogram of subject or sample weight (e.g., about 1 microgram per kilogram to about 500 milligrams per kilogram, about 100 micrograms per kilogram to about 5 milligrams per kilogram, or about 1 microgram per kilogram to about 50 micrograms per kilogram). Examples of doses of a protein or polypeptide include gram, milligram or microgram amounts per kilogram of subject or sample weight (e.g., about 1 microgram per kilogram to about 5 grams per kilogram, about 100 micrograms per kilogram to about 500 milligrams per kilogram, or about 1 milligram per kilogram to about 50 milligrams per kilogram). For antibodies, examples of dosages are from about 0.1 milligram per kilogram to 100 milligrams per kilogram of body weight (generally 10 milligrams per kilogram to 20 milligrams per kilogram). If the antibody is to act in the brain, a dosage of 50

milligrams per kilogram to 100 milligrams per kilogram is usually appropriate. It is furthermore understood that appropriate doses of one of these agents depend upon the potency of the agent with respect to the expression or activity to be modulated. Such appropriate doses can be determined using the assays described herein. When one or more of these agents is to be administered to an animal (e.g., a human) in order to modulate expression or activity of a polypeptide or nucleic acid of the invention, a physician, veterinarian, or researcher can, for example, prescribe a relatively low dose at first, subsequently increasing the dose until an appropriate response is obtained. In addition, it is understood that the specific dose level for any particular animal subject will depend upon a variety of factors including the activity of the specific agent employed, the age, body weight, general health, gender, and diet of the subject, the time of administration, the route of administration, the rate of excretion, any drug combination, and the degree of expression or activity to be modulated.

A pharmaceutical composition of the invention is formulated to be compatible with its intended route of administration. Examples of routes of administration include parenteral, e.g., intravenous, intradermal, subcutaneous, oral (e.g., inhalation), transdermal (topical), transmucosal, and rectal administration. Solutions or suspensions used for parenteral, intradermal, or subcutaneous application can include the following components: a sterile diluent such as water for injection, saline solution, fixed oils, polyethylene glycols, glycerine, propylene glycol or other synthetic solvents; antibacterial agents such as benzyl alcohol or methyl parabens; antioxidants such as ascorbic acid or sodium bisulfite; chelating agents such as ethylenediamine-tetraacetic acid; buffers such as acetates, citrates or phosphates; and agents for the adjustment of tonicity such as sodium chloride or dextrose. pH can be adjusted using acids or bases, such as hydrochloric acid or sodium hydroxide. The parenteral preparation can be enclosed in ampules, disposable syringes or multiple dose vials made of glass or plastic.

Pharmaceutical compositions suitable for injectable use include sterile aqueous solutions (where water soluble) or dispersions and sterile powders for the extemporaneous

preparation of sterile injectable solutions or dispersions. For intravenous administration, suitable carriers include physiological saline, bacteriostatic water, CREMOPHOR™ EL (BASF; Parsippany, NJ) or phosphate buffered saline (PBS). The composition should be sterile and should be fluid to the extent that easy syringability exists. It should be stable
5 under the conditions of manufacture and storage and should be preserved against the contaminating action of microorganisms such as bacteria and fungi. The carrier can be a solvent or dispersion medium containing, for example, water, ethanol, polyol (for example, glycerol, propylene glycol, and liquid polyethylene glycol, and the like), and suitable mixtures thereof. The proper fluidity can be maintained, for example, by the use of a coating
10 such as lecithin, by the maintenance of the required particle size in the case of dispersion and by the use of surfactants. Prevention of the action of microorganisms can be achieved by various anti-bacterial and anti-fungal agents, for example, parabens, chlorobutanol, phenol, ascorbic acid, thimerosal, and the like. In many cases, it will be preferable to include isotonic agents, for example, sugars, polyalcohols such as mannitol, sorbitol, or sodium
15 chloride in the composition. Prolonged absorption of the injectable compositions can be brought about by including in the composition an agent which delays absorption, for example, aluminum monostearate and gelatin.

Sterile injectable solutions can be prepared by incorporating the active compound (e.g., a polypeptide or antibody) in the required amount in an appropriate solvent with one or
20 a combination of ingredients enumerated above, as required, followed by filtered sterilization. Generally, dispersions are prepared by incorporating the active compound into a sterile vehicle which contains a basic dispersion medium, and then incorporating the required other ingredients from those enumerated above. In the case of sterile powders for the preparation of sterile injectable solutions, examples of methods of preparation are
25 vacuum drying and freeze-drying which yields a powder of the active ingredient plus any additional desired ingredient from a previously sterile-filtered solution thereof.

Oral compositions generally include an inert diluent or an edible carrier. They can be enclosed in gelatin capsules or compressed into tablets. For the purpose of oral therapeutic

administration, the active compound can be incorporated with excipients and used in the form of tablets, troches, or capsules. Oral compositions can also be prepared using a fluid carrier for use as a mouthwash, wherein the compound in the fluid carrier is applied orally and swished and expectorated or swallowed.

5 Pharmaceutically compatible binding agents, adjuvant materials, or both, can be included as part of the composition. The tablets, pills, capsules, troches, and the like can contain any of the following ingredients, or compounds of a similar nature: a binder such as microcrystalline cellulose, gum tragacanth or gelatin; an excipient such as starch or lactose, a
10 disintegrating agent such as alginic acid, PRIMOGEL™, or corn starch; a lubricant such as magnesium stearate or Sterotes; a glidant such as colloidal silicon dioxide; a sweetening agent such as sucrose or saccharin; or a flavoring agent such as peppermint, methyl salicylate, or orange flavoring.

 For administration by inhalation, the compounds are delivered in the form of an aerosol spray from a pressurized container or dispenser which contains a suitable propellant,
15 e.g., a gas such as carbon dioxide, or a nebulizer.

 Systemic administration can also be by transmucosal or transdermal means. For transmucosal or transdermal administration, penetrants appropriate to the barrier to be permeated are used in the formulation. Such penetrants are generally known in the art, and include, for example, for transmucosal administration, detergents, bile salts, and fusidic acid
20 derivatives. Transmucosal administration can be accomplished through the use of nasal sprays or suppositories. For transdermal administration, the active compounds are formulated into ointments, salves, gels, or creams as generally known in the art.

 The compounds can also be prepared in the form of suppositories (e.g., with conventional suppository bases such as cocoa butter and other glycerides) or retention
25 enemas for rectal delivery.

 In one embodiment, the active compounds are prepared with carriers that will protect the compound against rapid elimination from the body, such as a controlled release formulation, including implants and microencapsulated delivery systems. Biodegradable,

biocompatible polymers can be used, such as ethylene vinyl acetate, polyanhydrides, polyglycolic acid, collagen, polyorthoesters, and polylactic acid. Methods for preparation of such formulations will be apparent to those skilled in the art. The materials can also be obtained commercially from Alza Corporation and Nova Pharmaceuticals, Inc. Liposomal
5 suspensions (including liposomes having monoclonal antibodies incorporated therein or thereon) can also be used as pharmaceutically acceptable carriers. These can be prepared according to methods known to those skilled in the art, for example, as described in U.S. Patent No. 4,522,811.

It is especially advantageous to formulate oral or parenteral compositions in dosage
10 unit form for ease of administration and uniformity of dosage. Dosage unit form as used herein refers to physically discrete units suited as unitary dosages for the subject to be treated; each unit containing a predetermined quantity of active compound calculated to produce the desired therapeutic effect in association with the required pharmaceutical carrier. The specification for the dosage unit forms of the invention are dictated by and directly
15 dependent on the unique characteristics of the active compound and the particular therapeutic effect to be achieved, and the limitations inherent in the art of compounding such an active compound for the treatment of individuals.

Generally, partially human antibodies and fully human antibodies have a longer half-life within the human body than other antibodies. Accordingly, lower dosages and less
20 frequent administration is often possible. Modifications such as lipidation can be used to stabilize antibodies and to enhance uptake and tissue penetration (e.g., into the brain). A method for lipidation of antibodies is described by Cruikshank et al. ((1997) J. Acquired Immune Deficiency Syndromes and Human Retrovirology 14:193).

The nucleic acid molecules of the invention can be inserted into vectors and used as
25 gene therapy vectors. Gene therapy vectors can be delivered to a subject by, for example, intravenous injection, local administration (U.S. Patent 5,328,470), or by stereotactic injection (see, e.g., Chen et al. (1994) Proc. Natl. Acad. Sci. USA 91:3054-3057). The pharmaceutical preparation of the gene therapy vector can include the gene therapy vector in

an acceptable diluent, or can comprise a slow release matrix in which the gene delivery vehicle is imbedded. Alternatively, where the complete gene delivery vector can be produced intact from recombinant cells, e.g., retroviral vectors, the pharmaceutical preparation can include one or more cells which produce the gene delivery system.

5 It is recognized that the pharmaceutical compositions and methods described herein can be used independently or in combination with one another. That is, subjects can be administered one or more of the pharmaceutical compositions, e.g., pharmaceutical compositions comprising a nucleic acid molecule or protein of the invention or a modulator thereof, subjected to one or more of the therapeutic methods described herein, or both, in
10 temporally overlapping or non-overlapping regimens. When therapies overlap temporally, the therapies may generally occur in any order and can be simultaneous (e.g., administered simultaneously together in a composite composition or simultaneously but as separate compositions) or interspersed. By way of example, a subject afflicted with a disorder
15 described herein can be simultaneously or sequentially administered both a cytotoxic agent which selectively kills aberrant cells and an antibody (e.g., an antibody of the invention) which can, in one embodiment, be conjugated or linked with a therapeutic agent, a cytotoxic agent, an imaging agent, or the like.

The pharmaceutical compositions can be included in a container, pack, or dispenser together with instructions for administration.

20 V. Uses and Methods of the Invention

The nucleic acid molecules, proteins, protein homologs, and antibodies described herein can be used in one or more of the following methods: a) screening assays; b) detection assays (e.g., chromosomal mapping, tissue typing, forensic biology); c) predictive medicine
25 (e.g., diagnostic assays, prognostic assays, monitoring clinical trials, and pharmacogenomics); and d) methods of treatment (e.g., therapeutic and prophylactic). For example, polypeptides of the invention can be used for all of the purposes identified herein in portions of the disclosure relating to individual types of protein of the invention. The

isolated nucleic acid molecules of the invention can be used to express proteins (e.g., via a recombinant expression vector in a host cell in gene therapy applications), to detect mRNA (e.g., in a biological sample) or a genetic lesion, and to modulate activity of a polypeptide of the invention. In addition, the polypeptides of the invention can be used to screen drugs or compounds which modulate activity or expression of a polypeptide of the invention as well as to treat disorders characterized by insufficient or excessive production of a protein of the invention or production of a form of a protein of the invention which has decreased or aberrant activity compared to the wild type protein. In addition, the antibodies of the invention can be used to detect and isolate a protein of the and modulate activity of a protein of the invention.

This invention further pertains to novel agents identified by the above-described screening assays and uses thereof for treatments as described herein.

A. Screening Assays

The invention provides a method (also referred to herein as a "screening assay") for identifying modulators, i.e., candidate or test compounds or agents (e.g., peptides, peptidomimetics, small molecules or other drugs) which bind with a polypeptide of the invention or have a stimulatory or inhibitory effect on, for example, expression or activity of a polypeptide of the invention.

In one embodiment, the invention provides assays for screening candidate or test compounds which bind with or modulate the activity of the membrane-bound form of a polypeptide of the invention or biologically active portion thereof. The test compounds of the present invention can be obtained using any of the numerous approaches in combinatorial library methods known in the art, including: biological libraries; spatially addressable parallel solid phase or solution phase libraries; synthetic library methods requiring deconvolution; the "one-bead one-compound" library method; and synthetic library methods using affinity chromatography selection. The biological library approach is limited to peptide libraries,

while the other four approaches are applicable to peptide, non-peptide oligomer, or small molecule libraries of compounds (Lam (1997) *Anticancer Drug Des.* 12:145).

Examples of methods useful for the synthesis of molecular libraries can be found in the art, for example in: DeWitt et al. (1993) *Proc. Natl. Acad. Sci. USA* 90:6909; Erb et al. (1994) *Proc. Natl. Acad. Sci. USA* 91:11422; Zuckermann et al. (1994). *J. Med. Chem.* 37:2678; Cho et al. (1993) *Science* 261:1303; Carrell et al. (1994) *Angew. Chem. Int. Ed. Engl.* 33:2059; Carrell et al. (1994) *Angew. Chem. Int. Ed. Engl.* 33:2061; and Gallop et al. (1994) *J. Med. Chem.* 37:1233.

Libraries of compounds can be presented in solution (e.g., Houghten (1992) *Bio/Techniques* 13:412-421), or on beads (Lam (1991) *Nature* 354:82-84), chips (Fodor (1993) *Nature* 364:555-556), bacteria (U.S. Patent No. 5,223,409), spores (Patent numbers 5,571,698; 5,403,484; and 5,223,409), plasmids (Cull et al. (1992) *Proc. Natl. Acad. Sci. USA* 89:1865-1869) or phage (Scott and Smith (1990) *Science* 249:386-390; Devlin (1990) *Science* 249:404-406; Cwirla et al. (1990) *Proc. Natl. Acad. Sci. USA* 87:6378-6382; and Felici (1991) *J. Mol. Biol.* 222:301-310).

In one embodiment, an assay is a cell-based assay in which a cell which expresses a membrane-bound form of a polypeptide of the invention, or a biologically active portion thereof, on the cell surface is contacted with a test compound and the ability of the test compound to bind with the polypeptide is determined. The cell, for example, can be a yeast cell or a cell of mammalian origin. Determining the ability of the test compound to bind with the polypeptide can be accomplished, for example, by coupling the test compound with a radioisotope or enzymatic label such that binding of the test compound to the polypeptide or biologically active portion thereof can be determined by detecting the labeled compound in a complex. For example, test compounds can be labeled with ^{125}I , ^{35}S , ^{14}C , or ^3H , either directly or indirectly, and the radioisotope detected by direct counting of radio-emission or by scintillation counting. Alternatively, test compounds can be enzymatically labeled with, for example, horseradish peroxidase, alkaline phosphatase, or luciferase, and the enzymatic label detected by determination of conversion of an appropriate substrate to product. In one

embodiment, the assay comprises contacting a cell which expresses a membrane-bound form of a polypeptide of the invention, or a biologically active portion thereof, on the cell surface with a known compound which binds the polypeptide to form an assay mixture, contacting the assay mixture with a test compound, and determining the ability of the test compound to
5 interact with the polypeptide, wherein determining the ability of the test compound to interact with the polypeptide comprises determining the ability of the test compound to preferentially bind with the polypeptide or a biologically active portion thereof as compared to the known compound.

In another embodiment, the assay involves assessment of an activity characteristic of
10 the polypeptide, wherein binding of the test compound with the polypeptide or a biologically active portion thereof alters (i.e., increases or decreases) the activity of the polypeptide.

In another embodiment, an assay is a cell-based assay comprising contacting a cell expressing a membrane-bound form of a polypeptide of the invention, or a biologically active portion thereof, on the cell surface with a test compound and determining the ability of the
15 test compound to modulate (e.g., stimulate or inhibit) the activity of the polypeptide or biologically active portion thereof. Determining the ability of the test compound to modulate the activity of the polypeptide or a biologically active portion thereof can be accomplished, for example, by determining the ability of the polypeptide to bind with or interact with a target molecule or to transport molecules across the cytoplasmic membrane.

Determining the ability of a polypeptide of the invention to bind with or interact with
20 a target molecule can be accomplished by one of the methods described above for determining direct binding. As used herein, a "target molecule" is a molecule with which a selected polypeptide (e.g., a polypeptide of the invention binds or interacts with in nature, for example, a molecule on the surface of a cell which expresses the selected protein, a molecule
25 on the surface of a second cell, a molecule in the extracellular milieu, a molecule associated with the internal surface of a cell membrane or a cytoplasmic molecule. A target molecule can be a polypeptide of the invention or some other polypeptide or protein. For example, a target molecule can be a component of a signal transduction pathway which facilitates

transduction of an extracellular signal (e.g., a signal generated by binding of a compound to a polypeptide of the invention) through the cell membrane and into the cell or a second intercellular protein which has catalytic activity or a protein which facilitates association of downstream signaling molecules with a polypeptide of the invention. Determining the ability of a polypeptide of the invention to bind with or interact with a target molecule can be accomplished by determining the activity of the target molecule. For example, the activity of the target molecule can be determined by detecting induction of a cellular second messenger of the target (e.g., an mRNA, intracellular Ca^{2+} , diacylglycerol, IP3, and the like), detecting catalytic / enzymatic activity of the target on an appropriate substrate, detecting induction of a reporter gene (e.g., a regulatory element that is responsive to a polypeptide of the invention operably linked with a nucleic acid encoding a detectable marker, e.g., luciferase), or detecting a cellular response, for example, cellular differentiation, or cell proliferation.

In yet another embodiment, an assay of the present invention is a cell-free assay comprising contacting a polypeptide of the invention or biologically active portion thereof with a test compound and determining the ability of the test compound to bind with the polypeptide or biologically active portion thereof. Binding of the test compound with the polypeptide can be determined either directly or indirectly as described above. In one embodiment, the assay includes contacting the polypeptide of the invention or biologically active portion thereof with a known compound which binds the polypeptide to form an assay mixture, contacting the assay mixture with a test compound, and determining the ability of the test compound to interact with the polypeptide, wherein determining the ability of the test compound to interact with the polypeptide comprises determining the ability of the test compound to preferentially bind with the polypeptide or biologically active portion thereof as compared to the known compound.

In another embodiment, an assay is a cell-free assay comprising contacting a polypeptide of the invention or biologically active portion thereof with a test compound and determining the ability of the test compound to modulate (e.g., stimulate or inhibit) the activity of the polypeptide or biologically active portion thereof. Determining the ability of

the test compound to modulate activity of the polypeptide can be accomplished, for example, by determining the ability of the polypeptide to bind with a target molecule by one of the methods described above for determining direct binding. In an alternative embodiment, determining the ability of the test compound to modulate the activity of the polypeptide can
5 be accomplished by determining the ability of the polypeptide of the invention to further modulate the target molecule. For example, the catalytic activity, the enzymatic activity, or both, of the target molecule on an appropriate substrate can be determined as previously described.

In yet another embodiment, the cell-free assay comprises contacting a polypeptide of
10 the invention or biologically active portion thereof with a known compound which binds the polypeptide to form an assay mixture, contacting the assay mixture with a test compound, and determining the ability of the test compound to interact with the polypeptide. Ability of the test compound to interact with the polypeptide can be determined by assessing the ability of the polypeptide to preferentially bind with or modulate the activity of a target molecule, or
15 by any other method.

The cell-free assays of the present invention are amenable to use of either soluble or membrane-bound forms (where applicable) of a polypeptide of the invention. In the case of cell-free assays comprising a membrane-bound form of the polypeptide, it can be desirable to use a solubilizing agent in order to maintain the membrane-bound form of the polypeptide in
20 solution. Examples of such solubilizing agents include non-ionic detergents such as n-octylglucoside, n-dodecylglucoside, n-octylmaltoside, octanoyl-N-methylglucamide, decanoyl-N-methylglucamide, Triton X-100, Triton X-114, Thesit, isotridecylpoly(ethylene glycol ether)_n, 3-((3-cholamidopropyl) dimethylamminio)-1-propane sulfonate (CHAPS), 3-
25 ((3-cholamidopropyl) dimethylamminio)-2-hydroxy-1-propane sulfonate (CHAPSO), or N-dodecyl-N,N-dimethyl-3-ammonio-1-propane sulfonate.

In one or more embodiments of the above assay methods of the present invention, it can be desirable to immobilize either the polypeptide of the invention or its target molecule in order to facilitate separation of complexed and non-complexed forms of one or both of the

molecules, as well as to accommodate automation of the assay. Binding of a test compound with the polypeptide, or interaction of the polypeptide with a target molecule in the presence and absence of a candidate compound, can be accomplished in any vessel suitable for containing the reactants. Examples of such vessels include microtiter plates, test tubes, and micro-centrifuge tubes. In one embodiment, a fusion protein can be provided which adds a domain that allows one or both of the proteins to be bound to a matrix. For example, glutathione-S-transferase fusion proteins or glutathione-S-transferase fusion proteins can be adsorbed onto glutathione SEPHAROSE™ beads (Sigma Chemical; St. Louis, MO) or glutathione-derivatized microtiter plates, which are combined with the test compound and either the non-adsorbed target protein or a polypeptide of the invention. The combination is incubated under conditions conducive to complex formation (e.g., at physiological conditions for salt and pH). Following incubation, the beads or microtiter plate wells are washed to remove unbound components, and complex formation is measured directly or indirectly, for example, as described above. Alternatively, the complexes can be dissociated from the matrix, and the level of binding or activity of the polypeptide of the invention can be determined using standard techniques, such as those described herein.

Other techniques for immobilizing proteins on matrices can also be used in the screening assays of the invention. For example, either the polypeptide of the invention or a target molecule thereof (e.g., a protein which binds therewith or a substrate or an analog of a substrate of the protein of the invention) can be immobilized using conjugation of biotin and streptavidin. Biotinylated polypeptide of the invention or target molecules can be prepared using biotin-NHS (biotin-N-hydroxy-succinimide) using techniques well known in the art (e.g., using a commercially available kit such as the biotinylation kit manufactured by Pierce Chemical Co.; Rockford, IL), and immobilized in the wells of streptavidin-coated 96-well plates (Pierce Chemical). Alternatively, antibodies which are reactive with the polypeptide of the invention or target molecules but which do not interfere with binding of the polypeptide of the invention with its target molecule can be derivatized to the wells of the plate, and unbound target or polypeptide of the invention can be trapped in the wells by

antibody conjugation. Methods for detecting such complexes, in addition to those described above for the GST-immobilized complexes, include immunodetection of complexes using antibodies reactive with the polypeptide of the invention or target molecule, as well as enzyme-linked assays which rely on detecting an enzymatic activity associated with the polypeptide of the invention or target molecule.

In another embodiment, modulators of expression of a polypeptide of the invention are identified in a method in which a cell is contacted with a candidate compound and expression of the selected mRNA or protein (i.e., mRNA or protein corresponding to a polypeptide or nucleic acid of the invention) in the cell is determined. The level of expression of the selected mRNA or protein in the presence of the candidate compound is compared with the level of expression of the selected mRNA or protein in the absence of the candidate compound. The candidate compound can then be identified as a modulator of expression of the polypeptide of the invention based on this comparison. For example, if expression of the selected mRNA or protein is greater (i.e., statistically significantly greater) in the presence of the candidate compound than in its absence, then the candidate compound is identified as a stimulator of expression of the selected mRNA or protein. Alternatively, if expression of the selected mRNA or protein is less (i.e., statistically significantly less) in the presence of the candidate compound than in its absence, then the candidate compound is identified as an inhibitor of expression of the selected mRNA or protein. The level of the selected mRNA or protein expression in the cells can be determined by methods described herein.

In yet another aspect of the invention, a polypeptide of the invention can be used as a "bait protein" in a two-hybrid assay or three hybrid assay (see, e.g., U.S. Patent No. 5,283,317; Zervos et al. (1993) *Cell* 72:223-232; Madura et al. (1993) *J. Biol. Chem.* 268:12046-12054; Bartel et al. (1993) *Bio/Techniques* 14:920-924; Iwabuchi et al. (1993) *Oncogene* 8:1693-1696; and PCT Publication No. WO 94/10300), to identify other proteins which bind with or interact with the polypeptide of the invention and modulate activity of the polypeptide of the invention. Such binding proteins are also likely to be involved in the

propagation of signals by the polypeptide of the inventions as, for example, upstream or downstream elements of a signaling pathway involving the polypeptide of the invention.

This invention further pertains to novel agents identified by the above-described screening assays and uses thereof for treatments as described herein.

5

B. Detection Assays

Portions or fragments of the cDNA sequences identified herein (and the corresponding complete gene sequences) can be used in numerous ways as polynucleotide reagents. For example, these sequences can be used to: (i) map their respective genes on a chromosome and, thus, locate gene regions associated with genetic disease; (ii) identify an individual from a minute biological sample (tissue typing); and (iii) aid in forensic identification of a biological sample. These applications are described in the subsections below.

10

15

1. Chromosome Mapping

Once the sequence (or a portion of the sequence) of a gene has been isolated, this sequence can be used to map the location of the gene on a chromosome. Accordingly, nucleic acid molecules described herein or fragments thereof, can be used to map the location of the corresponding genes on a chromosome. Mapping of sequences to chromosomes is an important first step in correlating these sequences with genes associated with occurrence of disease. For example, the TANGO 457 gene maps to human chromosome 11p14.3; the TANGO 416 gene maps to human chromosome 4 between chromosomal markers D4S422 and D4S1576; the INTERCEPT 400 gene maps to human chromosome 4 between markers D4S1616 and D4S1611; the TANGO 331 gene maps to human chromosome 22 at 22q11-q13, between markers WI-4572 and WI-8917; the TANGO 265 gene maps to human chromosome 1 between markers D1S305 and D1S2635; and the TANGO 286 gene maps to human chromosome 22 at 22q12-13.

20

25

Briefly, genes can be mapped to chromosomes by preparing PCR primers (preferably 15-25 nucleotide residues in length) from the sequence of a gene of the invention. Computer analysis of the sequence of a gene of the invention can be used to rapidly select primers that do not span more than one exon in the genomic DNA, which would complicate the
5 amplification process. These primers can be used for PCR screening of somatic cell hybrids containing individual human chromosomes. Only those hybrids containing the human gene corresponding to the gene sequences will yield an amplified fragment. For a review of this technique, see D'Eustachio et al. ((1983) Science 220:919-924).

PCR mapping of somatic cell hybrids is a rapid procedure for assigning a particular
10 sequence to a particular chromosome. Three or more sequences can be assigned per day using a single thermal cycler. Using one or more nucleic acid sequences of the invention to design oligonucleotide primers, sub-localization can be achieved using panels of fragments prepared from specific chromosomes. Other mapping strategies which can similarly be used to map a gene to its chromosomal location include in situ hybridization (described in Fan et
15 al. (1990) Proc. Natl. Acad. Sci. USA 87:6223-27), pre-screening with labeled flow-sorted chromosomes, and pre-selection by hybridization with chromosome specific cDNA libraries. Fluorescence in situ hybridization (FISH) of a DNA sequence using a metaphase chromosomal spread can be used to provide a precise chromosomal location in one step. For a review of this technique, see Verma et al. (Human Chromosomes: A Manual of Basic
20 Techniques (Pergamon Press, New York, 1988)).

Reagents for chromosome mapping can be used individually to mark a single chromosome or a single site on a chromosome. Alternatively, panels of reagents can be used for marking multiple sites, multiple chromosomes, or both. Reagents corresponding to non-coding regions of the genes actually are preferred for mapping purposes. Coding sequences
25 are more likely to be conserved within gene families, thus increasing the chance of cross-hybridization during chromosomal mapping.

Once a sequence has been mapped to a precise chromosomal location, the physical position of the sequence on the chromosome can be correlated with genetic map data. (Such

data are found, for example, in V. McKusick, Mendelian Inheritance in Man, available on-line through Johns Hopkins University Welch Medical Library). The relationship between genes and disease, mapped to the same chromosomal region, can then be identified by linkage analysis (co-inheritance of physically adjacent genes), described in, e.g., Egeland et al. (1987) Nature 325:783-787.

Moreover, differences in the DNA sequences between individuals affected and non-affected with a disease associated with a gene of the invention can be determined. If a mutation is observed in some or all of the affected individuals, but not in any (or in very few) non-affected individuals, then the mutation is likely to be the causative agent of the particular disease. Comparison of affected and non-affected individuals generally involves first looking for structural alterations in the chromosomes such as deletions or translocations that are visible from chromosome spreads or detectable using PCR based on that DNA sequence. Ultimately, complete sequencing of genes from several individuals can be performed to confirm the presence of a mutation and to distinguish mutations from polymorphisms.

2. Tissue Typing

The nucleic acid sequences of the present invention can also be used to identify individuals from minute biological samples. The United States military, for example, is considering the use of restriction fragment length polymorphism (RFLP) for identification of its personnel. In this technique, an individual's genomic DNA is digested with one or more restriction enzymes, and probed on a Southern blot to yield unique bands for identification. This method does not suffer from the current limitations of physical identification devices such as general issue "dog tags," which can be lost, switched, or stolen, making positive identification difficult. The sequences of the present invention are useful as additional DNA markers for RFLP (described in U.S. Patent 5,272,057).

Furthermore, the sequences of the present invention can be used to provide an alternative technique which determines the actual base-by-base DNA sequence of selected portions of an individual's genome. The nucleic acid sequences described herein can be used

to prepare two PCR primers from the 5' and 3' ends of the sequences. These primers can then be used to amplify an individual's DNA and to subsequently sequence it.

Panels of corresponding DNA sequences from individuals, prepared in this manner, can provide unique individual identifications, because (with the exception of identical twins) every individual has a unique set of such DNA sequences owing, at least in part, to allelic differences. Sequences of the present invention can be used to obtain such identification sequences from individuals and from tissue. The nucleic acid sequences of the invention uniquely represent portions of the human genome. Allelic variation occurs to some degree in the coding regions of these sequences, and to a greater degree in the non-coding regions. It is estimated that allelic variation between individual humans occurs with a frequency of about once per 500 nucleotide residues. Each of the sequences described herein can, to some degree, be used as a standard against which DNA from an individual can be compared for identification purposes. Because greater numbers of polymorphisms occur in the non-coding regions, fewer non-coding sequences are necessary to differentiate individuals. The non-coding sequences of any of SEQ ID NOs: 1, 31, 51, 71, 81, 91, 96, 101, 106, 111, 121, 141, 151, 171, 181, 191, 201, 215, 221, 241, 251, 271, 279, 303, 308, 324, 329, 351, 371, 379, 387, 403, 415, 423, and 437 can comfortably provide positive individual identification with a panel of perhaps 10 to 1,000 primers which each yield a non-coding amplified sequence of 100 bases. If predicted coding sequences, such as those in any of SEQ ID NOs: 2, 32, 52, 72, 82, 92, 97, 102, 107, 112, 122, 142, 152, 162, 172, 182, 192, 202, 215, 222, 242, 252, 272, 280, 304, 309, 325, 330, 352, 362, 372, 380, 388, 404, 416, 424, and 438 are used, a more appropriate number of primers for positive individual identification would be 500-2,000.

If a panel of reagents from the nucleic acid sequences described herein is used to generate a unique identification database for an individual, those same reagents can later be used to identify nucleic acids, cells, or tissue from that individual. Using the unique identification database, positive identification of the individual, living or dead, can be made from extremely small samples.

3. Use of Partial Gene Sequences in Forensic Biology

DNA-based identification techniques can be used in forensic biology. Forensic biology is a scientific field employing genetic typing of biological evidence found at a crime scene as a means for positively identifying, for example, a perpetrator of a crime. To make such an identification, PCR technology can be used to amplify DNA sequences taken from very small biological samples such as tissues (e.g., hair or skin) or body fluids (e.g., blood, saliva, or semen) found at a crime scene. The amplified sequence can be compared with a standard, thereby allowing identification of the origin of the biological sample.

The sequences of the present invention can be used to provide polynucleotide reagents (e.g., PCR primers) targeted to specific loci in the human genome, which can enhance the reliability of DNA-based forensic identifications by, for example, providing another "identification marker" (i.e., another DNA sequence that is unique to a particular individual). As mentioned above, actual nucleotide sequence information can be used for identification as an accurate alternative to patterns formed by restriction enzyme-generated fragments. Sequences of non-coding regions are particularly appropriate for this use, because greater numbers of polymorphisms occur in non-coding regions, making it easier to differentiate individuals using this technique. Examples of polynucleotide reagents include the nucleic acid sequences of the invention or portions thereof, e.g., fragments derived from non-coding regions having a length of at least 20 or 30 nucleotide residues.

The nucleic acid sequences described herein can further be used to provide polynucleotide reagents, e.g., labeled or labelable probes which can be used in, for example, an in situ hybridization technique, to identify a specific tissue, e.g., brain tissue. This can be very useful in cases where a forensic pathologist is presented with a tissue of unknown origin. Panels of such probes can be used to identify tissue by species and/or by organ type.

C. Predictive Medicine

The present invention also pertains to the field of predictive medicine in which diagnostic assays, prognostic assays, and monitoring clinical trials are used for prognostic

(predictive) purposes to thereby treat an individual prophylactically. Accordingly, one aspect of the present invention relates to diagnostic assays for determining expression of a gene encoding a polypeptide of the invention as well as activity of a polypeptide of the invention, in the context of a biological sample (e.g., blood, serum, cells, tissue) to thereby determine whether an individual is afflicted with a disease or disorder, or is at risk of developing a disorder, associated with aberrant or unwanted expression of a gene encoding a polypeptide of the invention or aberrant or unwanted activity of a polypeptide of the invention. The invention also provides for prognostic (or predictive) assays for determining whether an individual is at risk of developing a disorder associated with a protein of the invention, with expression of a nucleic acid encoding a polypeptide of the invention, or with activity of a polypeptide of the invention. For example, mutations in a gene encoding a polypeptide of the invention can be assayed in a biological sample. Such assays can be used for prognostic or predictive purpose to thereby prophylactically treat an individual prior to the onset of a disorder characterized by or associated with a polypeptide of the invention, expression of a nucleic acid encoding it, or its activity.

As an alternative to making determinations based on the absolute expression level of selected genes, determinations may be based on the normalized expression levels of these genes. Expression levels are normalized by correcting the absolute expression level of a gene encoding a polypeptide of the invention by comparing its expression to the expression of a different gene, e.g., a housekeeping gene that is constitutively expressed. Suitable genes for normalization include housekeeping genes such as the actin gene. This normalization allows the comparison of the expression level in one sample (e.g., a patient sample), to another sample, or between samples from different sources.

Alternatively, the expression level can be provided as a relative expression level. To determine a relative expression level of a gene, the level of expression of the gene is determined for 10 or more samples of different endothelial (e.g. intestinal endothelium, airway endothelium, or other mucosal epithelium) cell isolates, preferably 50 or more samples, prior to the determination of the expression level for the sample in question. The mean expression level

of each of the genes assayed in the larger number of samples is determined and this is used as a baseline expression level for the gene(s) in question. The expression level of the gene determined for the test sample (absolute level of expression) is then divided by the mean expression value obtained for that gene. This provides a relative expression level and aids in identifying extreme cases of disorders associated with aberrant expression of a gene encoding a polypeptide of the invention protein or with aberrant expression of a ligand thereof.

Preferably, the samples used in the baseline determination will be from either or both of cells which aberrantly express a gene encoding a polypeptide of the invention or a ligand thereof (i.e. 'diseased cells') and cells which express a gene encoding a polypeptide of the invention at a normal level or a ligand thereof (i.e. 'normal' cells). The choice of the cell source is dependent on the use of the relative expression level. Using expression found in normal tissues as a mean expression score aids in validating whether aberrance in expression of a gene encoding a polypeptide of the invention occurs specifically in diseased cells. Such a use is particularly important in identifying whether a gene encoding a polypeptide of the invention can serve as a target gene. In addition, as more data is accumulated, the mean expression value can be revised, providing improved relative expression values based on accumulated data. Expression data from endothelial cells (e.g. mucosal endothelial cells) provides a means for grading the severity of the disorder.

Another aspect of the invention pertains to monitoring the influence of agents (e.g., drugs, antibodies, antisense oligonucleotides, or other compounds) on the expression or activity of a polypeptide of the invention in clinical trials.

These and other agents are described in further detail in the following sections.

1. Diagnostic Assays

An example of a method for detecting the presence or absence of a polypeptide or nucleic acid of the invention in a biological sample involves obtaining a biological sample from a test subject and contacting the biological sample with a compound or an agent capable of detecting a polypeptide or nucleic acid (e.g., mRNA, genomic DNA) of the invention. An

example of an agent for detecting mRNA or genomic DNA encoding a polypeptide of the invention is a labeled nucleic acid probe capable of hybridizing with mRNA or genomic DNA encoding a polypeptide of the invention. The nucleic acid probe can be, for example, a full-length cDNA, such as the nucleic acid of one of SEQ ID NOs: 1, 31, 51, 71, 81, 91, 96, 101, 106, 111, 121, 141, 151, 171, 181, 191, 201, 217, 221, 241, 251, 271, 279, 303, 308, 324, 329, 351, 371, 379, 387, 403, 415, 423, and 437, or a portion thereof, such as an oligonucleotide of at least 15, 30, 50, 100, 250 or 500 nucleotides in length and sufficient to specifically hybridize under stringent conditions with a mRNA or genomic DNA encoding a polypeptide of the invention. Other suitable probes for use in the diagnostic assays of the invention are described herein.

An example of an agent for detecting a polypeptide of the invention is an antibody capable of binding with a polypeptide of the invention, such as an antibody having a detectable label. Antibodies can be polyclonal or, preferably, monoclonal. An intact antibody, or a fragment thereof (e.g., Fab or F(ab')₂) can be used. The term "labeled," with regard to the probe or antibody, includes direct labeling of the probe or antibody by coupling (i.e., physically linking) a detectable substance to the probe or antibody, as well as indirect labeling of the probe or antibody by coupling it with another reagent that is directly labeled. Examples of indirect labeling include detection of a primary antibody using a fluorescently labeled secondary antibody and end-labeling of a DNA probe with biotin such that it can be detected with fluorescently labeled streptavidin. The term "biological sample" is intended to include tissues, cells, and biological fluids isolated from a subject, as well as tissues, cells, and fluids present within a subject. That is, the detection method of the invention can be used to detect mRNA, protein, or genomic DNA in a biological sample in vitro as well as in vivo. For example, in vitro techniques for detection of mRNA include Northern hybridization methods and in situ hybridization methods. In vitro techniques for detection of a polypeptide of the invention include enzyme linked immunosorbent assays (ELISAs), Western blots, immunoprecipitation, and immunofluorescence. In vitro techniques for detection of genomic DNA include Southern hybridizations. Furthermore, in vivo techniques

for detection of a polypeptide of the invention include introducing into a subject a labeled antibody directed against the polypeptide. For example, the antibody can be labeled with a radioactive marker, the presence and location of which in a subject can be detected using standard imaging techniques.

5 In one embodiment, the biological sample contains protein molecules obtained from the test subject. Alternatively, the biological sample can contain mRNA molecules obtained from the test subject or genomic DNA molecules obtained from the test subject. An example of a biological sample is a peripheral blood leukocyte-containing sample obtained by conventional means from a subject (e.g., isolated peripheral blood leukocytes).

10 In another embodiment, the methods further involve obtaining a control biological sample from a control (i.e., non-afflicted) subject, contacting the control sample with a compound or agent capable of detecting a polypeptide of the invention or mRNA or genomic DNA encoding a polypeptide of the invention. The presence or amount of the polypeptide, mRNA, or genomic DNA encoding the polypeptide in the control and test samples can be
15 compared to assess the degree, if any, to which the presence or amount in the test sample differs from that in the control sample.

The invention also encompasses kits for detecting the presence of a polypeptide or nucleic acid of the invention in a biological sample obtained from a subject. Such kits can be used to determine if a subject is suffering from or is at increased risk of developing a disorder
20 associated with aberrant expression of a polypeptide of the invention (e.g., one of the disorders described in the section of this disclosure wherein the individual polypeptide of the invention is discussed). For example, the kit can comprise a labeled compound or agent capable of detecting the polypeptide or mRNA encoding the polypeptide in a biological sample. The kit can also, or alternatively, contain means for determining the amount of the
25 polypeptide or mRNA in the sample (e.g., an antibody which specifically binds with the polypeptide or an oligonucleotide probe which binds with a nucleic acid encoding the polypeptide). Kits can include instructions for assessing whether the tested subject is suffering from or is at risk of developing a disorder associated with aberrant expression of

the polypeptide if the amount of the polypeptide or mRNA encoding the polypeptide is above or below a normal level.

For antibody-based kits, the kit can comprise, for example: (1) a first antibody (e.g., attached to a solid support) which specifically binds with a polypeptide of the invention; and, optionally, (2) a second, different antibody which specifically binds with either the polypeptide or the first antibody and is conjugated with a detectable agent.

For oligonucleotide-based kits, the kit can comprise, for example: (1) an oligonucleotide (e.g., a detectably labeled oligonucleotide) which hybridizes with a nucleic acid encoding a polypeptide of the invention or (2) a pair of primers useful for amplifying a nucleic acid encoding a polypeptide of the invention. The kit can comprise, for example, a buffering agent, a preservative, or a protein stabilizing agent. The kit can also comprise components necessary for detecting the detectable agent (e.g., an enzyme or a substrate). The kit can contain a control sample or a series of control samples which can be assayed and compared with the test sample assay results. Each component of the kit can be enclosed within an individual container and all of the various containers can furthermore be within a single package, optionally with instructions for assessing whether the tested subject is suffering from or is at risk of developing a disorder associated with aberrant expression of the polypeptide.

2. Prognostic Assays

The methods described herein can furthermore be used as diagnostic or prognostic assays to identify subjects having or at risk of developing a disease or disorder associated with aberrant expression or activity of a polypeptide of the invention (e.g., one of the disorders described in the section of this disclosure wherein the individual polypeptide of the invention is discussed). Thus, the present invention provides a method in which a test sample is obtained from a subject and a polypeptide or nucleic acid (e.g., mRNA, genomic DNA) of the invention is detected, wherein the presence, level, or activity of the polypeptide

or nucleic acid in the sample is associated with an enhanced or diminished risk of developing a disease or disorder associated with aberrant expression or activity of the polypeptide.

Furthermore, the prognostic assays described herein can be used to determine whether an agent (e.g., an agonist, antagonist, peptidomimetic, protein, peptide, nucleic acid, small molecule, or other drug candidate) can be administered to a subject in order to treat a disease or disorder associated with aberrant expression or activity of a polypeptide of the invention. For example, such methods can be used to determine whether a subject can be effectively treated using a specific agent or class of agents (e.g., agents of a type which decrease activity of the polypeptide). Thus, the present invention provides methods for determining whether an agent can be administered to a subject in order to effectively treat a disorder associated with aberrant expression or activity of a polypeptide of the invention. When efficacious agents are known or found, such assays can also be used to estimate an efficacious dose of the agent.

The methods of the invention can be used to detect genetic lesions or mutations in a gene of the invention in order to assess if a subject having the lesioned or mutated gene is at risk for a disorder characterized aberrant expression or activity of a polypeptide of the invention. In certain embodiments, the methods include detecting, in a sample of cells obtained from the subject, the presence or absence of a genetic lesion or mutation characterized by at least one of an alteration affecting the integrity of a gene encoding the polypeptide of the invention, or the mis-expression of the gene encoding the polypeptide of the invention. For example, such genetic lesions or mutations can be detected by ascertaining the existence of at least one of: 1) a deletion of one or more nucleotides from the gene; 2) an addition of one or more nucleotides to the gene; 3) a substitution of one or more nucleotides of the gene; 4) a chromosomal rearrangement of the gene; 5) an alteration in the level of a messenger RNA transcript of the gene; 6) an aberrant modification of the gene, such as of the methylation pattern of the genomic DNA; 7) a non-wild type splicing pattern of a messenger RNA transcript of the gene; 8) a non-wild type level of the protein encoded by the gene; 9) an allelic loss of the gene; and 10) an inappropriate post-translational

modification of the protein encoded by the gene. As described herein, there are a large number of assay techniques known in the art which can be used for detecting such lesions and mutations in a gene.

In certain embodiments, detection of the lesion involves the use of an oligonucleotide primer in a polymerase chain reaction (PCR; see, e.g., U.S. Patent Nos. 4,683,195 and 4,683,202), such as anchor PCR or RACE PCR, or, alternatively, in a ligation chain reaction (LCR; see, e.g., Landegran et al. (1988) Science 241:1077-1080; and Nakazawa et al. (1994) Proc. Natl. Acad. Sci. USA 91:360-364), the latter of which can be particularly useful for detecting point mutations in a gene (see, e.g., Abravaya et al. (1995) Nucleic Acids Res. 23:675-682). This method can include the steps of collecting a sample of cells from a patient, isolating nucleic acid (e.g., genomic, mRNA, or both) from the cells of the sample, contacting the nucleic acid sample with one or more primers which specifically hybridize with the selected gene under conditions such that hybridization and amplification of the gene (if present) occurs, and detecting the presence or absence of an amplification product. The method can also include detecting the size of the amplification product and comparing the length to the length of a corresponding product obtained in the same manner from a control sample. PCR, LCR, or both can be used as a preliminary amplification step in conjunction with any of the techniques used for detecting mutations described herein.

Alternative amplification methods include: self-sustained sequence replication (Guatelli et al. (1990) Proc. Natl. Acad. Sci. USA 87:1874-1878), transcriptional amplification system (Kwoh, et al. (1989) Proc. Natl. Acad. Sci. USA 86:1173-1177), Q-Beta Replicase (Lizardi et al. (1988) Bio/Technology 6:1197), or any other nucleic acid amplification method, followed by the detection of the amplified molecules using any of a variety of techniques well known to those of skill in the art. These detection schemes are especially useful for detection of nucleic acid molecules if such molecules are present in very low numbers.

In an alternative embodiment, mutations in a selected gene can be identified in a sample by detecting alterations in restriction enzyme cleavage patterns. For example, sample

and control DNA is isolated, (optionally) amplified, digested with one or more restriction endonucleases, and fragment length sizes are determined by gel electrophoresis and compared. Differences in fragment length sizes between sample and control DNA indicates occurrence of mutations or other sequence differences in the sample DNA. Moreover,
5 sequence specific ribozymes (see, e.g., U.S. Patent No. 5,498,531) can be used to score for the presence of specific mutations by development or loss of a ribozyme cleavage site.

In other embodiments, genetic mutations are identified by hybridizing a sample and control nucleic acids, e.g., DNA or RNA, with high density arrays containing hundreds or thousands of oligonucleotide probes (Cronin et al. (1996) *Human Mutation* 7:244-255;
10 Kozal et al. (1996) *Nature Medicine* 2:753-759). For example, genetic mutations can be identified using two-dimensional arrays of light-generated DNA probes fixed to a surface, as described in Cronin et al., supra. Briefly, a first hybridization array of probes can be used to scan through long stretches of DNA in a sample and control to identify base changes between the sequences by making linear arrays of sequential overlapping probes. This step allows the
15 identification of point mutations. This step is followed by hybridization of the nucleic acid sample with a second hybridization array in order to characterize specific mutations using smaller, specialized probe arrays complementary to many or all potential variants or mutations. Each mutation array is composed of parallel probe sets, one complementary to the wild-type gene and the other complementary to the mutant gene.

20 In yet another embodiment, any of a variety of sequencing methods known in the art can be used to directly sequence the selected gene and detect mutations by comparing the sequence of the sample nucleic acids with the corresponding wild-type (control) sequence. Examples of sequencing reactions include those based on techniques developed by Maxim and Gilbert ((1977) *Proc. Natl. Acad. Sci. USA* 74:560) or Sanger ((1977) *Proc. Natl. Acad. Sci. USA* 74:5463). It is also contemplated that any of a variety of automated sequencing
25 procedures can be used when performing the diagnostic assays ((1995) *Bio/Techniques* 19:448), including sequencing by mass spectrometry (see, e.g., PCT Publication No. WO

94/16101; Cohen et al. (1996) *Adv. Chromatogr.* 36:127-162; and Griffin et al. (1993) *Appl. Biochem. Biotechnol.* 38:147-159).

Other methods for detecting mutations in a selected gene include methods in which protection from cleavage agents is used to detect mismatched bases in RNA / RNA or RNA / DNA heteroduplexes (Myers et al. (1985) *Science* 230:1242). In general, the technique of mismatch cleavage entails providing heteroduplexes formed by hybridizing (labeled) RNA or DNA containing the wild-type sequence with potentially mutant RNA or DNA obtained from a tissue sample. The double-stranded duplexes are treated with an agent that cleaves single-stranded regions of the duplex such as those which exist due to base pair mismatches between the control and sample strands. RNA / DNA duplexes can be treated with RNase to digest mismatched regions, and DNA / DNA hybrids can be treated with S1 nuclease to digest mismatched regions.

In other embodiments, DNA / DNA or RNA / DNA duplexes can be treated with hydroxylamine or osmium tetroxide and with piperidine in order to digest mismatched regions. After digestion of the mismatched regions, the resulting material is separated by size on denaturing polyacrylamide gels to determine the site of the mutated or mismatched region. See, e.g., Cotton et al. (1988) *Proc. Natl. Acad. Sci. USA* 85:4397; Saleeba et al. (1992) *Methods Enzymol.* 217:286-295. In one embodiment, the control DNA or RNA is labeled for detection.

In still another embodiment, the mismatch cleavage reaction employs one or more proteins that recognize mismatched base pairs in double-stranded DNA (so called DNA mismatch repair enzymes) in defined systems for detecting and mapping point mutations in cDNAs obtained from samples of cells. For example, the mutY enzyme of *E. coli* cleaves following A residues at G / A mismatches and the thymidine DNA glycosylase from HeLa cells cleaves following T residues at G / T mismatches (Hsu et al. (1994) *Carcinogenesis* 15:1657-1662). According to one embodiment, a probe based on a selected sequence, e.g., a wild-type sequence, is hybridized with a cDNA or other DNA product obtained from a test cell(s). The duplex is treated with a DNA mismatch repair enzyme, and the cleavage

products, if any, are detected using an electrophoresis protocol or another polynucleotide-separating method. See, e.g., U.S. Patent No. 5,459,039.

In other embodiments, alterations in electrophoretic mobility are used to identify mutations in genes. For example, single strand conformation polymorphism (SSCP) analysis can be used to detect differences in electrophoretic mobility between mutant and wild type nucleic acids (Orita et al. (1989) *Proc. Natl. Acad. Sci. USA* 86:2766; see also Cotton (1993) *Mutat. Res.* 285:125-144; Hayashi (1992) *Genet. Anal. Tech. Appl.* 9:73-79). Single-stranded DNA fragments of sample and control nucleic acids are denatured and allowed to re-nature. The secondary structure of single-stranded nucleic acids varies according to their nucleotide sequence, and the resulting alteration in electrophoretic mobility enables detection of even a single base change. The DNA fragments can be labeled or detected using labeled probes. The sensitivity of the assay can be enhanced by using RNA (rather than DNA), because the secondary structure of RNA is more sensitive to sequence changes. In one embodiment, the method uses heteroduplex analysis to separate double stranded heteroduplex molecules on the basis of changes in electrophoretic mobility (Keen et al. (1991) *Trends Genet.* 7:5).

In yet another embodiment, the movement of mutant or wild-type fragments in polyacrylamide gels containing a gradient of denaturant is assayed using denaturing gradient gel electrophoresis (DGGE), as described (Myers et al. (1985) *Nature* 313:495). When DGGE is used as the method of analysis, DNA is modified to ensure that it does not completely denature, for example by adding a 'GC clamp' of approximately 40 nucleotide residues of high-melting GC-rich DNA to one or both ends of the DNA strands, for example using a PCR method. In a further embodiment, a temperature gradient is used in place of a denaturing gradient to identify differences in the mobility of control and sample DNA (Rosenbaum and Reissner (1987) *Biophys. Chem.* 265:12753).

Examples of other techniques for detecting point mutations include, but are not limited to, selective oligonucleotide hybridization, selective amplification, and selective primer extension. For example, oligonucleotide primers can be prepared in which the known

mutation is located centrally. The primers are hybridized with target DNA under conditions which permit hybridization only if a perfect complementary nucleotide sequence match occurs (Saiki et al. (1986) Nature 324:163); Saiki et al. (1989) Proc. Natl. Acad. Sci. USA 86:6230). Such allele specific oligonucleotides are hybridized with PCR-amplified target
5 DNA or attached to a surface for hybridization.

Alternatively, allele specific amplification technology can be used in conjunction with the methods of the invention. Oligonucleotides used as primers for specific amplification have a sequence complementary to the nucleotide sequence of a mutation of interest in the center of the molecule, so that occurrence of amplification depends on
10 occurrence of the mutation in the sample nucleic acid (Gibbs et al. (1989) Nucleic Acids Res. 17:2437-2448) or at the extreme 3' end of one primer where, under appropriate conditions, mismatching can prevent or inhibit polymerase extension (Prossner (1993) Tibtech 11:238). In addition, it can be desirable to introduce a novel restriction site in the region of the mutation in order to facilitate cleavage-based detection (Gasparini et al. (1992) Mol. Cell
15 Probes 6:1). Amplification can be performed using Taq ligase (Barany (1991) Proc. Natl. Acad. Sci. USA 88:189). In such cases, ligation will occur only if there is a perfect match at the 3' end of the 5' sequence, thereby making it possible to assess the presence of a known mutation at a specific site by looking for the presence or absence of amplification.

The methods described herein can be performed, for example, using pre-packaged
20 diagnostic kits comprising at least one probe nucleic acid or antibody reagent described herein. Such kits can be used, for example, in clinical settings to diagnose patients exhibiting symptoms or a family history of a disorder involving a gene encoding a polypeptide of the invention. Furthermore, any cell type or tissue in which the polypeptide of the invention is expressed (e.g., a blood sample containing peripheral blood leukocytes for proteins which are
25 secreted or which occur on or in peripheral blood leukocytes) can be used in the prognostic assays described herein.

3. Pharmacogenomics

Agents which have a stimulatory or inhibitory effect on activity or expression of a polypeptide of the invention, as identified by a screening assay described herein for example, can be administered to individuals to treat (prophylactically or therapeutically) disorders associated with aberrant activity of the polypeptide. In conjunction with such treatment, the pharmacogenomics (i.e., the study of the relationship between an individual's genotype and that individual's response to a foreign compound or drug) of the individual can be considered. Differences in metabolism of therapeutics can lead to severe toxicity or therapeutic failure by altering the relation between dose and blood concentration of the pharmacologically active drug. Thus, the pharmacogenomics of the individual permits selection of effective agents (e.g., drugs) for prophylactic or therapeutic treatments based on a consideration of the individual's genotype. Such pharmacogenomics can further be used to determine appropriate dosages and therapeutic regimens. Accordingly, the activity of a polypeptide of the invention, expression of a nucleic acid of the invention, or mutation content of a gene of the invention in an individual can be determined to facilitate selection of one or more appropriate agents for therapeutic or prophylactic treatment of the individual.

Pharmacogenomics deals with clinically significant hereditary variations in the response to drugs due to altered drug disposition and abnormal action in affected persons. See, e.g., Linder (1997) Clin. Chem. 43(2):254-266. In general, two types of pharmacogenetic conditions can be differentiated. Genetic conditions transmitted as a single factor altering the way drugs act on the body are referred to as "altered drug action." Genetic conditions transmitted as single factors altering the way the body acts on drugs are referred to as "altered drug metabolism". These pharmacogenetic conditions can occur either as rare defects or as polymorphisms. For example, glucose-6-phosphate dehydrogenase (G6PD) deficiency is a common inherited enzymopathy in which the main clinical complication is hemolysis after ingestion of oxidant drugs (anti-malarials, sulfonamides, analgesics, nitrofurans) and consumption of fava beans.

As an illustrative embodiment, the activity of drug metabolizing enzymes is a major determinant of both the intensity and duration of drug action. The discovery of genetic polymorphisms of drug metabolizing enzymes (e.g., N-acetyltransferase 2 {NAT 2} and cytochrome P450 enzymes CYP2D6 and CYP2C19) explains why some patients do not obtain the expected drug effects or exhibit exaggerated drug response and serious toxicity following administration of standard and safe doses of a drug. These polymorphisms are expressed in two phenotypes in the population, the extensive metabolizer (EM) and poor metabolizer (PM). The prevalence of PM is different among different populations. For example, the gene encoding CYP2D6 is highly polymorphic, and several mutations have been identified in PM. Each of these mutations results in absence of functional CYP2D6. Poor metabolizers of CYP2D6 and CYP2C19 frequently experience exaggerated drug response and side effects when they receive standard doses. If a metabolite is the active therapeutic moiety, a PM will show no therapeutic response, as demonstrated for the analgesic effect of codeine mediated by its CYP2D6-formed metabolite morphine. At the other extreme are the so called ultra-rapid metabolizers who do not respond to standard doses. Recently, the molecular basis of ultra-rapid metabolism has been identified to be due to CYP2D6 gene amplification.

Thus, activity of a polypeptide of the invention, expression of a nucleic acid encoding the polypeptide, or mutation content of a gene encoding the polypeptide in an individual can be determined to facilitate selection of appropriate agents for therapeutic or prophylactic treatment of the individual. In addition, pharmacogenetic studies can be used to apply genotyping of polymorphic alleles encoding drug-metabolizing enzymes to identification of an individual's drug responsiveness phenotype. This knowledge, when applied to dosing or drug selection, can avoid adverse reactions or therapeutic failure and thus enhance therapeutic or prophylactic efficiency when treating a subject with a modulator of activity or expression of the polypeptide, such as a modulator identified by one of the examples of screening assays described herein.

4. Monitoring of Effects During Clinical Trials

Monitoring the influence of agents (e.g., drug compounds) on expression or activity of a polypeptide of the invention (e.g., ability to modulate aberrant cell proliferation chemotaxis, differentiation, or both) can be applied not only in basic drug screening, but also in clinical trials. For example, the effectiveness of an agent, as determined by a screening assay as described herein, to increase gene expression, protein levels, or protein activity can be monitored in clinical trials of subjects exhibiting decreased gene expression, protein levels, or protein activity. Alternatively, the effectiveness of an agent, as determined by a screening assay, to decrease gene expression, protein levels, or protein activity can be monitored in clinical trials of subjects exhibiting increased gene expression, protein levels, or protein activity. In such clinical trials, expression or activity of a polypeptide of the invention and, optionally, that of other polypeptide that have been implicated in similar disorders, can be used as a marker of the immune responsiveness of a particular cell.

For example, genes (including those of the invention) that are modulated in cells by treatment with an agent (e.g., a peptide, a drug, or another small molecule) which modulates activity or expression of a polypeptide of the invention (e.g., as identified in a screening assay described herein) can be identified. Thus, to study the effect of agents on cellular proliferation disorders, for example, in a clinical trial, cells can be isolated and their RNA can be prepared and analyzed to determine the level of expression of one or more genes of the invention and, optionally, other genes implicated in the disorder. The levels of gene expression (i.e., a gene expression pattern) can be quantified by Northern blot analysis or by RT-PCR, as described herein, or by assessing the amount of protein produced, by one of the methods as described herein, or by measuring the level of activity of a gene of the invention or other gene(s). In this way, the gene expression pattern can serve as an indicator of the physiological response of the cells to the agent. Accordingly, this response state can be determined before, and at various points during, or after treatment of the individual with the agent (or, of course, at more than one of these stages).

In one embodiment, the present invention provides a method for monitoring the effectiveness of treatment of a subject with an agent (e.g., an agonist, antagonist, peptidomimetic, protein, peptide, nucleic acid, small molecule, or other drug candidate identified by the screening assays described herein) comprising (i) obtaining a pre-administration sample from a subject prior to administration of the agent; (ii) detecting the level of the polypeptide or nucleic acid of the invention in the pre-administration sample; (iii) obtaining one or more post-administration samples from the subject; (iv) detecting the level of the polypeptide or nucleic acid of the invention in the post-administration sample(s); (v) comparing the level of the polypeptide or nucleic acid of the invention in the pre-administration sample with the level of the polypeptide or nucleic acid of the invention in the post-administration sample(s); and (vi) altering the administration of the agent to the subject accordingly. For example, increased administration of the agent can be desirable to increase the expression or activity of the polypeptide to levels higher than those detected, i.e., to increase the effectiveness of the agent. Alternatively, decreased administration of the agent can be desirable to decrease expression or activity of the polypeptide to levels lower than those detected, i.e., to decrease the effectiveness of the agent.

C. Methods of Treatment

The present invention provides both prophylactic and therapeutic methods of treating a subject afflicted with, at risk for developing, or susceptible to a disorder associated with aberrant expression or activity of a polypeptide of the invention. Such disorders are described elsewhere in this disclosure.

1. Prophylactic Methods

In one aspect, the invention provides a method for preventing in a subject, a disorder associated with aberrant expression or activity of a polypeptide of the invention, by administering to the subject an agent which modulates expression of the polypeptide or at least one activity of the polypeptide. Subjects at risk for a disease which is caused or

contributed to by aberrant expression or activity of a polypeptide of the invention can be identified by, for example, any one or combination of the diagnostic and prognostic assays described herein. Administration of a prophylactic agent can occur prior to the manifestation of symptoms characteristic of the aberrance, so that the disease or disorder is prevented or, alternatively, delayed in its onset or progression. Depending on the type of aberrance, for example, an agonist or antagonist agent can be used for treating the subject. The appropriate agent can be determined based on screening assays described herein.

2. Therapeutic Methods

Another aspect of the invention pertains to methods of modulating expression or activity of a polypeptide of the invention for therapeutic purposes. The modulatory method of the invention involves contacting a cell with an agent that modulates one or more of the activities of the polypeptide. An agent that modulates activity can be an agent as described herein, such as a nucleic acid, or a protein, a naturally-occurring cognate ligand of the polypeptide, a peptide, a peptidomimetic, or a small molecule. In one embodiment, the agent stimulates one or more of the biological activities of the polypeptide. Examples of such stimulatory agents include a polypeptide of the invention, a biologically active portion of such a polypeptide, a portion of such a polypeptide which comprises an epitope of the native polypeptide, and a nucleic acid molecule encoding the polypeptide of the invention that has been introduced into the cell. In another embodiment, the agent inhibits a biological activity of the polypeptide of the invention or expression of a protein or nucleic acid of the invention. Examples of such inhibitory agents include antisense nucleic acid molecules and antibodies. These modulatory methods can be performed in vitro (e.g., by culturing the cell with the agent) or, alternatively, in vivo (e.g., by administering the agent to a subject). As such, the present invention provides methods of treating an individual afflicted with a disease or disorder characterized by aberrant expression or activity of a polypeptide of the invention. In one embodiment, the method involves administering an agent (e.g., an agent identified by a screening assay described herein), or combination of agents that modulates (e.g., up-regulates

or down-regulates) expression or activity. In another embodiment, the method involves administering a polypeptide of the invention or a nucleic acid molecule of the invention as therapy to compensate or substitute for reduced or aberrant expression or activity of the polypeptide.

5 Stimulation of activity is desirable in situations in which activity or expression is abnormally low or in which increased activity is likely to have a beneficial effect. Conversely, inhibition of activity is desirable in situations in which activity or expression is abnormally high or in which decreased activity is likely to have a beneficial effect.

Deposits of Clones

15 Clones containing one or more cDNA molecules encoding polypeptides of the invention have been deposited with the American Type Culture Collection (ATCC®; 10801 University Boulevard, Manassas, VA 20110-2209) on dates disclosed herein, and these deposits were assigned the Accession Numbers disclosed herein. These deposits will be maintained under the terms of the Budapest Treaty on the International Recognition of the Deposit of Microorganisms for the Purposes of Patent Procedure. These deposits were made merely as a convenience for those of skill in the art and are not an admission that any deposit is required in
20 order to comply with 35 U.S.C. §112.

25 Where a clone containing multiple cDNA molecules was deposited, the following standard digest procedure can be used to liberate fragments corresponding to individual cDNA molecules, except as otherwise described. To isolate the cDNA clone, an aliquot of the deposited clone can be streaked out to yield single colonies on nutrient medium (e.g., Luria broth plates) supplemented with 100 micrograms per milliliter ampicillin. Single colonies are grown, and plasmid DNA is extracted from single colonies using a standard mini-preparation procedure. Next, a sample of the DNA mini-preparation is digested using a combination of the

restriction enzymes Sal I and Not I, and the resulting products are resolved on a 0.8% (w/v) agarose gel using standard DNA electrophoresis conditions.

A clone containing a cDNA molecule encoding TANGO 416 (clone EpT416), was deposited with the American Type Culture Collection (ATCC®; 10801 University Boulevard,
5 Manassas, VA 20110-2209) on April 26, 1999 as Accession Number PTA-1764, as an *Escherichia coli* strain carrying a recombinant plasmid harboring the clone. The standard digest procedure liberates a fragment as follows:

TANGO 416 (EpT416): 5.1 kilobases.

The identity of the strain containing TANGO 416 can be inferred from the liberation of a
10 fragment of the above identified size.

A clone containing a cDNA molecule encoding TANGO 457 (clone 457), was deposited with the ATCC® on October 1, 1999 as Accession Number PTA-817, as part of a composite deposit representing a mixture of four strains, each carrying one recombinant plasmid harboring a particular cDNA clone. The standard digest procedure liberates a fragment
15 as follows:

TANGO 457 (457): 2.3 kilobases

The identity of the strain containing TANGO 457 can be inferred from the liberation of a fragment of the above identified size.

Clones containing cDNA molecules encoding TANGO 229 and INTERCEPT 289
20 (clones EpT229 and EpI289, respectively), were deposited with the ATCC® on October 1, 1999 as Accession No. PTA-295, as part of a composite deposit representing a mixture of four strains, each carrying one recombinant plasmid harboring a particular cDNA clone. The standard digest procedure liberates fragments as follows:

TANGO 229 (EpT229): 3.6 kilobases

25 INTERCEPT 289 (EpI289): 1.9 kilobases

The identity of the strains can be inferred from the fragments liberated.

Clones containing cDNA molecules encoding INTERCEPT 429 (clone EpI429), were deposited with the ATCC® on August 5, 1999 as Accession No. PTA-455, as part of a

composite deposit representing a mixture of three strains, each carrying one recombinant plasmid harboring a particular cDNA clone. The standard digest procedure liberates a fragment as follows:

INTERCEPT 429 (EpI429): 0.5 kilobase

- 5 The identity of the strain containing INTERCEPT 429 can be inferred from the liberation of a fragment of the above identified size.

Clones containing cDNA molecules encoding INTERCEPT 309 and MANGO 419 (clones EpT309 and EpT419, respectively), were deposited with the ATCC® on January 6, 2000 as Accession Number PTA-1156, as part of a composite deposit representing a mixture of
10 four strains, each carrying one recombinant plasmid harboring a particular cDNA clone. The standard digest procedure liberates fragments as follows:

TANGO 309 (EpT309): 1.9 kilobases

MANGO 419 (EpT419): 0.3 kilobases

The identity of the strains can be inferred from the fragments liberated.

- 15 Clones containing cDNA molecules encoding TANGO 366 and INTERCEPT 394 (clones Aped and 394, respectively), were deposited with the ATCC® on July 23, 1999 as Accession No. PTA-424, as part of a composite deposit representing a mixture of five strains, each carrying one recombinant plasmid harboring a particular cDNA clone. The standard digest procedure liberates fragments as follows:

20 TANGO 366 (EpT366): 2.6 kilobase pairs

INTERCEPT 394 (394): 3.7 kilobase pairs

The identity of the strains can be inferred from the fragments liberated.

- Clones containing cDNA molecules encoding TANGO 210 and INTERCEPT 400 (clones Aped and 400, respectively), were deposited with the ATCC® on July 29, 1999 as
25 Accession No. PTA-438, as part of a composite deposit representing a mixture of five strains, each carrying one recombinant plasmid harboring a particular cDNA clone. The standard digest procedure liberates fragments as follows:

TANGO 210 (EpT210): 1.7 kilobase pairs

INTERCEPT 400 (400): 3.0 kilobase pairs

The identity of the strains can be inferred from the fragments liberated.

Clones comprising cDNA molecules encoding human INTERCEPT 217, human INTERCEPT 297, and human TANGO 331 were deposited with ATCC® on May 28, 1999, as
5 part of a composite deposit representing a mixture of five strains, each carrying one recombinant plasmid harboring a particular cDNA clone. This deposit was assigned Accession Number PTA-147. The standard digest procedure (except that restriction enzymes Sall, NotI, and SmaI are used) liberates fragments as follows:

1. human INTERCEPT 217 (clone EpT217): 2.9 kilobases
- 10 2. human INTERCEPT 297 (clone EpT297): 1.2 kilobases and 0.3 kilobases (human INTERCEPT 297 has a SmaI cut site at about base pair 1183).
3. human TANGO 331 (clone EpT331): 1.4 kilobases

The identity of the strains can be inferred from the fragments liberated.

Human TANGO 276, human TANGO 292, human TANGO 332, human TANGO 202,
15 human TANGO 234, and human TANGO 265 were each deposited as single deposits. Their clone names, deposit dates, and accession numbers are as follows:

1. human TANGO 276: clone EpT276 was deposited with ATCC® on May 28, 1999, and was assigned Accession Number PTA-150.
2. human TANGO 292: clone EpT292 was deposited with ATCC® on April 28, 1999,
20 and was assigned Accession Number 207230.
3. human TANGO 332: clone EpT332 was deposited with ATCC® on May 28, 1999, and was assigned Accession Number PTA-151.
4. human TANGO 202: clone EpT202 was deposited with ATCC® on April 21, 1999, and was assigned Accession Number 207219.
- 25 5. human TANGO 234: clone EpT234 was deposited with ATCC® on April 2, 1999, and was assigned Accession Number 207184.
6. human TANGO 265: clone EpT265 was deposited with ATCC® on April 28, 1999, and was assigned Accession Number 207228.

Clones containing cDNA molecules encoding human TANGO 286, human TANGO 294, and INTERCEPT 296 were deposited with ATCC® on April 21, 1999 as Accession Number 207220, as part of a composite deposit representing a mixture of five strains, each carrying one recombinant plasmid harboring a particular cDNA clone. The standard digest procedure (except that restriction enzymes Sall, NotI, and DraII are used) liberates fragments as follows:

1. human TANGO 286 (clone EpT286): 1.85 kilobases and .1 kilobases (human TANGO 286 has a DraII cut site at about base pair 1856).
2. human TANGO 294 (clone EpT294): 1.4 kilobases and .6 kilobases (human TANGO 294 has a DraII cut site at about base pair 1447).
3. human INTERCEPT 296 (clone EpT296): .4 kilobases, 1.6 kilobases, and .1 kilobases (human INTERCEPT 296 has DraII cut sites at about base pair 410 and at about base pair 1933).

The identity of the strains can be inferred from the fragments liberated.

A clone containing a cDNA molecule encoding mouse TANGO 202 was deposited with ATCC® on April 21, 1999 and was assigned Accession Number 207221, as part of a composite deposit representing a mixture of five strains, each carrying one recombinant plasmid harboring a particular cDNA clone. The standard digest procedure (except that restriction enzymes Sall, NotI, and ApaI are used) liberates a fragment as follows:

- mouse TANGO 202 (clone EpTm202): 3.5 kilobases and 1.4 kilobases (mouse TANGO 202 has a Apa I cut site at about base pair 3519).

The identity of the strain can be inferred from the fragment liberated.

Equivalents

Those skilled in the art will recognize, or be able to ascertain using no more than routine experimentation, many equivalents to the specific embodiments of the invention described herein. Such equivalents are encompassed by the following claims.
